

# A L<sup>A</sup>T<sub>E</sub>X Primer

## Required Reading for Seekers of T<sub>E</sub>X Support

Benedikt Wilde\*

Revision from 2020-10-22

In the past, I have frequently given T<sub>E</sub>Xnical support to others. While I enjoy spreading the good news of L<sup>A</sup>T<sub>E</sub>X, repeating the same general advice over and over started getting rather time-consuming and a bit tiresome. This document is meant to replace that initial session of conveying basic knowledge and good practices as well as serve as a reference for these things. It is *not* meant to discourage you from approaching me with questions or problems regarding L<sup>A</sup>T<sub>E</sub>X, though I may refuse to explain things contained in this document.

# 1 Introduction

## 1.1 What This Document Is

This document is a list of things that everybody working with  $\LaTeX$  should know. Many sections explain concepts and guidelines that are usually the first things I tell people when giving  $\TeX$  support. Some of them are just good practice, others are serious mistakes that way too many people make.

This document is a rather minimal reference. If you are unsure what packages to load or which macros and environments to use for some standard task, you should find them here. Of course, this list isn't anywhere close to exhaustive.

Mainly, though, this document is a jumping-off point for people wanting to improve their  $\LaTeX$  writing or ask me for help with that. Hopefully, I can reach more people with it than by individual coaching. When I do give personal advice, it shall serve me as a solid foundation I can refer to and expect to be read. If you are thinking of asking me to review your  $\TeX$  file or about some specific  $\TeX$ nicl issue, please do, but first at least skim through this document.

## 1.2 What This Document Is Not

This document is not a tutorial. If you have never even seen a  $\LaTeX$  document, you will need to find help elsewhere. Preferably, ask someone who knows the stuff to help you set it up for the first time and create your first document. [learnlatex]<sup>1</sup> and [overleaf-doc]<sup>2</sup> may also be good starting points.

This document is not the whole truth. In fact, it isn't even nothing but the truth. In the spirit of Donald Knuth [Knu84], I choose to sometimes bend the truth or omit exceptions in order to make things easier to explain at first. Unlike Knuth, though, I will not clear up all of these inaccuracies later in the text. You will have to turn to other works for the full truth.

This document is not a completed work or infallible. If you spot mistakes or typos, find some passage confusing or want to request the inclusion of some aspects that I omitted, please send me an email at `benedikt.wilde@uni-tuebingen.de`.

## 1.3 Do I Have to Read All of This?

No. I would like everyone to read sections 4 through 9 at some point. Other than that, it really depends on your needs. Have a look at the table of contents to get an idea of what's interesting to you. Here's a summary of what's in which section.

- Section 2 clarifies the basic terminology of  $\TeX$  and  $\LaTeX$ . If the differences between  $\TeX$ ,  $\varepsilon\text{-}\TeX$ ,  $\LaTeX$ ,  $\text{pdf}\LaTeX$  and  $\text{Lua}\LaTeX$  confuse you, consider reading it.
- Section 3 explains how to set up  $\LaTeX$  and  $\TeX$ studio on your computer and suggests some configuration. If your configuration differs significantly from this recommendation and you ask me for help or to look over your document, I may complain.

---

<sup>1</sup><https://www.learnlatex.org/>

<sup>2</sup><https://www.overleaf.com/learn>

- Section 4 briefly lists some foundational knowledge about  $\LaTeX$  that anyone who has worked with it for some time should already be familiar with. If that is you, maybe skim through it anyway, just in case that you have been using  $\LaTeX$  oblivious to some basic knowledge.
- Sections 5 through 9 discuss matters of good practice regarding both the source file and the finished product of your document. *Everyone* should read these! The concepts describe there will significantly improve your documents and make writing them easier.
- Section 10 offers an overview of the most important document classes. If you are unsure which one is right for your document, read it.
- Section 11 does the same for packages. You should definitely read section 11.1. Read the other subsections depending on what you need in your document.
- Section 12 lists many common macros and environments. This is the most reference-like part of this document. Read only the parts you need.
- Section 13 explains how macros work on a technical level and how to define your own. Don't read this if you are just starting out with  $\LaTeX$ . Once you are a bit familiar with it and start wanting to write your own macros, however, it is a good idea to get a grip on the inner workings of macro expansion, which you can hopefully achieve by reading this section.
- Section 14 contains some information on how to deal with errors and where to find help regarding  $\LaTeX$  and its packages. If you are an absolute beginner, it is better to just ask someone you know who is not. Otherwise, do read this section.
- Section 15 lists all the websites, package documentations and other references mentioned in this document.

## 2 What It's All About

### 2.1 $\TeX$ and $\LaTeX$

Let's get some nomenclature out of the way first.  $\TeX$  is the name of both a program that translates text files into beautifully typeset documents (if used properly) and the language that is used to describe the document in the text file. This language consist of a couple hundred of primitive commands and the possibility to write macros, which allows the creation of  $\TeX$  programs to solve complex typesetting tasks with a simple user interface. When its creator, Donald Knuth, published  $\TeX$  in *The  $\TeX$ book* [Knu84] in 1984, he already included a small collection of useful macros in addition to the primitive commands, which together are referred to as plain  $\TeX$ .

Due to its usefulness for publications especially in the sciences and mathematics,  $\TeX$  was soon widely adopted in those fields and many authors created large macro systems to make working with  $\TeX$  more convenient. The most prominent of those is  $\LaTeX$  (originally created

by and named after Leslie Lamport), which today is the de facto standard for work with  $\text{T}_{\text{E}}\text{X}$ . (There are others, most notably  $\text{ConT}_{\text{E}}\text{Xt}$ , which I do not really know and will not mention further in this document.)  $\text{\LaTeX}$  introduced a more standardized structure to macros and documents (document classes, packages, environments and optional arguments as you (will) know them are all  $\text{\LaTeX}$  concepts) that allowed authors to easily share collections of macros with others as packages and document classes. Today there are thousands of  $\text{\LaTeX}$  packages freely available online that cover virtually all needs most document authors could have.

The current version of  $\text{\LaTeX}$  is called  $\text{\LaTeX} 2_{\epsilon}$  and was released in 1994 [Lam94]. Since then, it has only been modified very conservatively, fixing bugs and performing some changes to make it more suitable to new technological standards (e.g. UTF-8 support). When I write “ $\text{\LaTeX}$ ” in this document, I am referring to  $\text{\LaTeX} 2_{\epsilon}$ .

A lot of work has gone into developing a future version of  $\text{\LaTeX}$  with major improvements since the late nineties, called  $\text{\LaTeX} 3$ . This development is still underway and nowhere close to finished. The programming layer of  $\text{\LaTeX} 3$  is however rather advanced and functional already and offers tremendous advantages to programming in plain  $\text{T}_{\text{E}}\text{X}$ . So, if you ever consider writing a complex macro or even your own package, consider reading up on that.

## 2.2 The Output Format

Originally,  $\text{T}_{\text{E}}\text{X}$  output documents in the DVI format, specially developed for this purpose, and the program `tex` (and its derivative `latex`) still outputs this format. Since then, the PDF format has been developed and become the standard for digital documents. If you don't have very good reasons not to do so, you should thus use `pdfLaTeX` instead of `latex`. Since this is the default configuration of any modern  $\text{\LaTeX}$  editor, you need not worry about this unless you are compiling manually from the command line.

## 2.3 Extensions

There are several extensions to the original  $\text{T}_{\text{E}}\text{X}$ , adding new primitives and functionality. I will briefly present the most important ones here.

Firstly, there is  $\epsilon\text{-T}_{\text{E}}\text{X}$  (*extended  $\text{T}_{\text{E}}\text{X}$* ) which adds some new primitives to  $\text{T}_{\text{E}}\text{X}$  that make writing and modifying macros easier. This extension is now the default version of  $\text{T}_{\text{E}}\text{X}$ ; when you run `pdfLaTeX`,  $\epsilon\text{-T}_{\text{E}}\text{X}$  commands are available, so you don't need to worry about it.

Then there are  $\text{LuaT}_{\text{E}}\text{X}$  and  $\text{Lua}\text{\LaTeX}$ . Lua is a lightweight programming language designed to be embedded into other applications.  $\text{LuaT}_{\text{E}}\text{X}$  does this with  $\text{T}_{\text{E}}\text{X}$ , allowing access to the  $\text{T}_{\text{E}}\text{X}$  internals and manipulating them with a more natural programming language. This also allows the use of OTF fonts, which means that you can load any installed font on your machine in  $\text{Lua}\text{\LaTeX}$ . If you want to use packages that need Lua or load a font not available in `pdfLaTeX`, just use it, you only need to change the compilation program from `pdfLaTeX` to `luaLaTeX`. If you don't need those features, I recommend sticking with `pdfLaTeX` for now, since it compiles faster.

I also want to mention  $\text{X}_{\text{La}}\text{\LaTeX}$ , which is an extension developed for Mac OS and available on other operating systems with reduced functionality. Its main feature originally was the

extended font support, when Lua $\text{\LaTeX}$  was not available yet. Nowadays however, I would not recommend using X $\text{\LaTeX}$  unless you really need it for some reason.

### 3 Installation and Setup

In order to write Documents using  $\text{\LaTeX}$ , you need several programs on your computer. Most importantly, you need the  $\text{\LaTeX}$  program itself. Secondly, you need a text editor. Any text editor works, but there are specialized so-called  $\text{\LaTeX}$  editors that have useful features like code highlighting and completion, an integrated PDF viewer and more. I recommend using  $\text{\TeX}$ studio for this. Thirdly, you will probably not want to type out your bibliography database file yourself, as this is rather tiresome and it is difficult to search through the raw text file. There are editors for this, too, that offer a more natural handling of the database and manage the text file for you in the background. I recommend using JabRef for this.

#### 3.1 Installing $\text{\LaTeX}$

There are two major distributions you can choose from in order to install  $\text{\LaTeX}$  on your computer; MiK $\text{\TeX}$  and  $\text{\TeX}$  Live, which you can download from their websites<sup>3,4</sup>. Both of them contain the usual  $\text{\TeX}$  engines (plain  $\text{\TeX}$ , pdf $\text{\LaTeX}$ , Lua $\text{\LaTeX}$ , etc.) and most packages on the *Comprehensive  $\text{\TeX}$  Archive Network*<sup>5</sup> (CTAN). Here are the most important differences between them, some more are listed in [miktex-vs-texlive]<sup>6</sup>.

- MiK $\text{\TeX}$  is only available for Windows. This also means that it can focus on Windows more and has a more natural feel for Windows users.  $\text{\TeX}$  Live is also available for Linux and MacOS.
- By default,  $\text{\TeX}$  Live installs all of its packages (which entails several gigabytes of small file downloads) while MiK $\text{\TeX}$  only installs a small selection of packages and adds more as needed on the fly. You can also get a full MiK $\text{\TeX}$  installation right away or select what to install in  $\text{\TeX}$  Live, but that requires manual intervention.
- $\text{\TeX}$  Live only contains packages that are free software. This rarely makes a difference as all important packages are free and you can easily add non-free packages yourself.

In the end, you can just pick one if you are on Windows, otherwise you have to use  $\text{\TeX}$  Live.

#### 3.2 Installing $\text{\TeX}$ studio and JabRef

You can download  $\text{\TeX}$ studio and JabRef from their websites<sup>7,8</sup> and install them as usual. To get the most from these programs, some configuration is in order. You can either load the

<sup>3</sup><https://miktex.org/download>

<sup>4</sup><https://www.tug.org/texlive/acquire-netinstall.html>

<sup>5</sup><https://ctan.org/>

<sup>6</sup><https://tex.stackexchange.com/q/20036>

<sup>7</sup><https://texstudio.org/>

<sup>8</sup><https://jabref.org/>

settings I recommend by importing the files in the `preferences/` folder accompanying this document by

- placing `texstudio.ini` into the folder `%appdata%/texstudio/` and
  - loading `jabref_config.xml` using the Import preferences button in the JabRef settings
- or you can perform all of them manually. Here is a list of all the changes I performed before exporting the settings files mentioned above. Note that some of these settings are specific to the operating system (I used Windows) or how you installed the programs.

**TeXstudio** In the menu, open Options, Configure TeXstudio... and select Show Advanced Options in the bottom left corner. On the left side you will find a list of categories in which the preferences are grouped.

### General

- Set Max. Recent Documents to “12”.
- Set Max. Recent Master Documents to “7”.

### Commands

- Uncheck all buttons for repeating compilation commands.

### Build

- Uncheck all buttons for repeating compilation commands.
- Set Default Bibliography Tool to “`txs:///biber`”.
- Uncheck Check and update bibliography before compiling.
- Uncheck Show messages when starting compiling.
- Change Show stdout to “Always (If not redirected > /dev/null)”.

### Editor

- Change Indentation Mode to “Keep Indentation”.
- Check Replace Indentation Tab by Spaces.
- Check Replace Tab in Text by Spaces.
- Change Show Line Numbers to “All Line Numbers”.

### Adv. Editor

- Change Tab Width to “2”.
- Change Line Wrapping to “No Line Wrap”.

### Completion

- Uncheck Automatically start completer when typing LaTeX-Commands.

### Language Checking

- Change Default Language to “`de_DE`”.
- Change Thesaurus Database to  
“`C:/Program Files (x86)/texstudio/dictionaries/th_de_DE_v2.dat`”.

### Preview

- Uncheck Show preview as tooltip on formulas in editor.

You may also want to hide the “Central” button bar of the TeXstudio window.

**JabRef** In the menu, open Options, Preferences. Again, there is a list of categories of preferences on the left side of the window.

**General**

- Set Default bibliography mode to “BIBLATEX”.

**BibTeX key generator**

- Set default key pattern to “[auth:lower][year]”.
- Set book key pattern to “[auth:lower][year][veryshorttitle]”.

**Appearance**

- Select Dark theme.

**3.3 Allowing T<sub>E</sub>X to Call External Programs**

Sometimes you want T<sub>E</sub>X to call an external program, for example to prepare you bibliography, to convert an image or to parse some program code you want to show. On the other hand, it is a substantial security risk if you compile a document you did not write yourself and allow that document to execute *any code* on your computer. Because of this, both MiK<sub>T</sub>E<sub>X</sub> and T<sub>E</sub>X Live restrict T<sub>E</sub>X to only be able to call a select few external programs, like `biber` or `makeindex`.

Escaping to the shell from T<sub>E</sub>X is also referred to as `\write18` after the T<sub>E</sub>X primitive used to do it. If you want to lift the shell escape restrictions, you can run `LTEX` with the option `-shell-escape`. You can add it to the command your editor uses to compile documents in its preferences, but you should then be careful when compiling foreign documents. Instead, it may be better to only allow shell escape on a per-document basis, see below.

**3.4 Per-Document Configuration Using Magic Comments**

You can specify how an editor should handle a file with so-called *magic comments*. These are lines of text, usually at the beginning of the file, that start with `% !`. To T<sub>E</sub>X, these are normal comments and they are thus ignored. Editors, however, can parse these lines and adapt their behavior accordingly.

Not all editors support the same set of magic comments or any at all. Here is a list of magic comments supported by T<sub>E</sub>Xstudio.

`% !TeX encoding = utf8` specifies the character encoding of the file to be UTF-8. Note that this does *not* actually change the encoding or change how T<sub>E</sub>X reads the file. It only affects how the T<sub>E</sub>Xstudio reads the file.

`% !TeX spellcheck = de_DE` specifies the language T<sub>E</sub>Xstudio should use for spell checking.

`% !TeX program = pdflatex` specifies that T<sub>E</sub>Xstudio should use `pdflatex` to compile the document (as specified in the Commands section of the settings).

`% !TeX root = filename` specifies the root document of the current file to be `filename`. This is useful when separating the preamble or chapters of a document into separate files. For example, if your main document file is called `document.tex` and your preamble is in a separate file `preamble.tex`, you should add the magic comment `% !TeX root = document` to the preamble.

`% !TeX TXS-program:bibliography = txs:///biber` is a T<sub>E</sub>Xstudio-specific magic comment. It allows you to change any of the commands set in the Commands section of the settings, this one selects `biber` as the bibliography tool. As another example, if you want to compile the current document with Lua<sub>T</sub>E<sub>X</sub> with shell escape enabled, you could use `% !TeX TXS-program:compile = txs:///lualatex/[-shell-escape]`.

### 3.5 Keeping Things up to Date

Most of the thousands of packages that make up the L<sup>A</sup>T<sub>E</sub>X ecosystem are continuously maintained and improved. In order to receive bug-fixes and be able to use the latest features, you should regularly update your L<sup>A</sup>T<sub>E</sub>X distribution at least every couple of months. You can do this in your distribution's package manager (called *MiKTeX Console* in MiK<sub>T</sub>E<sub>X</sub> and *TeX Live Manager* in T<sub>E</sub>X Live). If you are using T<sub>E</sub>X Live, you will additionally have to install a new version every year.

While this does not usually happen, there is always the possibility that an update will break something. This is especially true if you use some evil hack exploiting the undocumented internals of a package (which is more common than one might expect). Thus, if you have a deadline coming up (say you are in the last phases of writing a thesis or a paper) and everything is working fine, you should *not* update until after that project is finished.

### 3.6 A Word on Overleaf

*Overleaf*<sup>9</sup> is a service for writing and compiling L<sup>A</sup>T<sub>E</sub>X documents online. While it has its merits, especially if you need to collaborate with other people on the same document or for people who are new to L<sup>A</sup>T<sub>E</sub>X and want to try it without having to set it up on their own machine first, I generally recommend working on a local installation rather than using Overleaf. Especially for large projects, it is much easier if you have direct access to and control over all of the files (including temporary files) belonging to that project.

One obvious example of this is being able to just open and modify an image that is included by your document, or to examine the auxiliary files produced by L<sup>A</sup>T<sub>E</sub>X when something does not work as desired. Another possible downside of Overleaf may be that its L<sup>A</sup>T<sub>E</sub>X installation (as well as other software you may want to use, e.g. Inkscape) is always lagging behind the current release a bit, so new features and bug-fixes are not immediately available there. The advantages and disadvantages of using Overleaf will vary depending on your project, of course, but in general a local installation is to be preferred.

## 4 Very, Very Basic Stuff

### 4.1 Special Characters

Most of the characters you type into your L<sup>A</sup>T<sub>E</sub>X file will appear as that character in the finished document. Some of them have a special meaning, though.

---

<sup>9</sup><https://www.overleaf.com/>

- \ (escape character)
- { (begin grouping)
- } (end grouping)
- \$ (math shift)
- & (alignment tab)
- # (macro parameter)
- ^ (math superscript)
- \_ (math subscript)
- % (comment character)
- There are some *active* characters that act like macros, usually ~ and " are relevant.

In order to print these characters to your document, you will have to use appropriate macros. Spaces and end of line characters are a bit special, too, see section 4.5.

## 4.2 What You Absolutely Need To Know About Macros

- A macro is a command that “does something”.
- Macros names consist of a backslash (\) followed by either an arbitrary number of letters (this is called a *control word*) or by exactly one non-letter (this is called a *control symbol*). Either is referred to as a *control sequence*.
- If a control word is followed by space characters, they are ignored (cf. section 4.5).
- Macros can take arguments.
  - ◊ Mandatory arguments are placed in braces, `\section{Something Cool}`, for example, starts a new section with the heading “Something Cool”.
  - ◊ Optional arguments are placed in brackets and may be omitted, for example `\section[Something]{Something Cool But Really Long}` starts a new section with the heading “Something Cool But Really Long” which appears as “Something” in the table of contents.
- `\begin` and `\end` are special macros that start and end *environments*. They take one mandatory argument, the environment name. Environments affect everything between these two macros, for example the `center` environment centers everything between `\begin{center}` and `\end{center}` (and adds some vertical space, too).
- Sometimes there are starred versions of macros or environments that behave slightly different, for example `\section*{Something Cool}` will produce an unnumbered section.

## 4.3 What You Absolutely Need To Know About Groups

Usually, options and macro definitions are set locally, i.e. their effect stops at the end of the current group. A group is delimited by braces (`{` and `}`) or by `\begingroup` and `\endgroup`. Environments also form groups. As an example, consider `\scshape`. It switches to small caps, but when it is enclosed in a group, the font switches back after the end of the group.

This text {will be \scshape in small caps. But not} for long.

This text will be IN SMALL CAPS. BUT NOT for long.

Note that when a macro consumes an argument that is enclosed in braces, the braces are removed. In order to group the argument's content, you will need to add an extra layer of braces (unless the macro takes care of this for you).

## 4.4 The Structure of a Document

Let's look at a minimal  $\text{\LaTeX}$  document.

```
\documentclass{article}

\begin{document}

Hello World!

\end{document}
```

Any  $\text{\LaTeX}$  document has to start with `\documentclass`, include `\begin{document}` and end with `\end{document}`. The part between before `\begin{document}` is called the *preamble* of the document. Anything after `\end{document}` will be ignored.

The document class provides the framework for your document, it sets up the main layout and makes essential macros for sectioning available (cf. section 10). The preamble cannot contain any typeset material. In it, you should load packages (cf. section 11), change options and create or modify macros (if you know what you are doing; cf. section 13).

The document proper is written between `\begin{document}` and `\end{document}`. Any text you write here will be printed onto the pages of your document.

## 4.5 Spaces and Newlines

- A space in the source maps to a space in the document.
- Several spaces are like one space.
- Single newlines are like a space.
- Spaces at the start of lines are ignored.

This means that all these spaces don't even do anything.

This means that all these spaces don't even do anything.

- An empty line (or a line containing only spaces) starts a new paragraph.
- Several empty lines are like one.

Here is a paragraph that is broken up into lines by `\TeX`. When the paragraph is finished, I leave a blank line.

This starts a new paragraph that is again broken up into lines by `\TeX`. Oh, the circle of life\dots

Here is a paragraph that is broken up into lines by `TEX`. When the paragraph is finished, I leave a blank line.

This starts a new paragraph that is again broken up into lines by `TEX`. Oh, the circle of life...

Since control words (i.e. pretty much all macros) gobble up subsequent spaces, you have to be careful if you want to insert a space directly after a macro. `\LaTeX` is great! would print “`\LaTeX` is great!”.

- You can use the macro `\`  (a backslash followed by a space) after the macro, which inserts a space: `\LaTeX\ is great!`
- You can put an empty group after the macro, so the space is no longer the next thing: `\LaTeX{} is great!`
- You can enclose the macro in a group: `{\LaTeX} is great!`

Note that the last option will also enclose any local definitions or assignments the macro performs in the group, preventing them from affecting the rest of the text.

## 4.6 Switching To and From Math Mode

You can switch to and from inline math mode using `\(` and `\)`.

In a right triangle `\(a^2 + b^2 = c^2\)` holds.

In a right triangle  $a^2 + b^2 = c^2$  holds.

For display math mode, use `\[` and `\]`.

`\[`  
`\sum_{k = 1}^{\infty} 2^{-k} = 1 = (\sin x)^2 + (\cos x)^2`  
`\]`

$$\sum_{k=1}^{\infty} 2^{-k} = 1 = (\sin x)^2 + (\cos x)^2$$

For displayed math there is a number of environments with different spacing, alignment and numbering properties, see section 12.6.

In math mode the spacing rules are different and considerably more complicated than in text mode. Space characters in the source don’t have any effect (except for termination control words and improving readability). There must not be any blank lines in math mode!

Letters are always typeset as variables, unless you specify otherwise. Many macros may only be used either in text or in math mode.

You will see many people using the primitive  $\text{T}_{\text{E}}\text{X}$  math shift `$` instead of the  $\text{L}^{\text{A}}\text{T}_{\text{E}}\text{X}$  macros `\(` and `\)` to switch to and from inline math mode. While this does the same thing, it is clearer and more consistent to use the latter (cf. section 5.1). You must *never ever* use the  $\text{T}_{\text{E}}\text{X}$  switch for display math (`$$`)!

## 4.7 Dimensions

Whenever  $\text{T}_{\text{E}}\text{X}$  expects a length, you can specify it in one of several units. Here are the most important ones (a complete list is given in [tex-units]<sup>10</sup>).

- `mm` and `cm` mean what you would expect. If you prefer (or are forced to use) stupid units, there is also `in` for inches.
- `pt` for typographic points.  $72.27 \text{ pt} = 1 \text{ in}$ . The font size in this document is set to 11 pt.
- `em` and `ex` are relative units that depend on the current font. It is often best to specify dimensions using these units, so that the choice still makes sense when your font (size) changes. 1 `em` is the width of a `\quad` and about the width of the letter M. 1 `ex` is about the height of the letter x. The intention is to for `em` to be used for horizontal and `ex` for vertical lengths, though that is not enforced in any way. Here are a square of 1 `em` and 1 `ex` width, respectively (remember that they may have different proportions with different fonts): 

There are also variables that contain dimensions. Their names look like macros, but they contain a length instead of an expansion. Here are the most important ones.

- `\textwidth` and `\textheight` for the size of the type area.
- `\columnwidth` for the width of the current column of text (in most documents this is the same as `\textwidth`).
- `\linewidth` for the width of the current line of text.

When  $\text{T}_{\text{E}}\text{X}$  expects a length, instead of providing it explicitly, you can use a dimension variable. You may prefix the variable with a numeric factor, which will result in the product of the factor and the length stored in the variable being used.

Both in the numeric values of explicit dimensions and in factors preceding dimension variables, all leading zeros may be omitted.

Let us list some examples for clarity.

- `\hspace{.5em}` will create a horizontal space of 0.5 `em` width.
- `\vspace{4ex}` will create a vertical space of 4 `ex` height.
- `\includegraphics[width=.6\linewidth]{cute_cat}` will include the requested picture scaled to a width of 60 % of the line width.

<sup>10</sup><https://tex.stackexchange.com/a/41371>

## 4.8 Compiling Enough Times

$\text{\LaTeX}$  reads your  $\text{\TeX}$  file top to bottom and creates your document page by page. This means that, when outputting a page, it does not know what will be on subsequent pages or if there will even be any. Because of this, auxiliary files are needed in order to facilitate things like a table of contents and cross references. When running  $\text{\LaTeX}$ , information necessary for these document elements is written to these files and left there for the next  $\text{\LaTeX}$  run. On the next run, this information is now present right from the start.

A consequence of this is that you often have to run  $\text{\LaTeX}$  *twice* before your table of contents or your references get updated. Many editors try to detect this and compile enough times automatically. However, this does not always work reliably. Furthermore, it can be quite irritating to have to wait for  $\text{\LaTeX}$  to finish several times when you just wanted to quickly compile while writing, e.g. to check the appearance of some math expression. Because of this, I prefer to disable this automatic guessing of necessary compilations and to just do it manually before publishing.

Another factor that necessitates extra compilation runs are external tools. Some packages use external programs to prepare some information for the next  $\text{\LaTeX}$  run. Examples are `biber` for bibliographic data and `makeindex` or `xindy` for index/glossary preparation. With them, you need to run  $\text{\LaTeX}$  first, then these tools, and then  $\text{\LaTeX}$  twice more.

## 5 First Principles

In my opinion, the two main things that make  $\text{\LaTeX}$  a superior typesetting system for authors are the following:

- All its endlessly flexible features are readily available just via typing.
- It allows (and in fact encourages) the separation of design from content.

The first point means that you can type your text without having to raise your hands from the keyboard to tediously click through menus and find just the right symbol or function. This is not only useful for technical writing where mathematical typesetting is needed. Texts in the humanities or non-academic writing, too, can be riddled with citations, cross references and special formatting of single words or phrases. Or maybe you want to have an index for your document? No problem, you just need to type the appropriate commands.

The second point frees you to write your text without having to decide the whole layout in advance. You can easily set a placeholder definition for, say, brand names and decide later on if you want to typeset them in italic or sans serif font, in a different color or with a box around them. Or maybe you don't want to use no special markup at all? You don't have to decide right away, that can wait until right before publication. This also makes it incredibly easy to get a consistent style across different documents or even with different authors. In addition, all the preferences are stored in a text file, can easily be copied and modified even long after the document was first written.

There are more advantages of  $\text{\LaTeX}$  over other typesetting software, like the fact that it is virtually infinitely backwards compatible, available on all platforms and that it makes it rather hard to commit the worst typographical sins. The fact that the document is stored as

a simple text file is also a big advantage as the whole file is human-readable and can easily be managed using common version control software like *Git*<sup>11</sup>. For the process of writing, however, the two points listed above are, I think, most relevant. The magnitude of these is hard to convey to someone who has no experience with  $\LaTeX$  and is maybe intimidated by its non-WYSIWYG user interface, and many a  $\LaTeX$  users may not have learned how to take full advantage of them. I will try to outline some principles here, that should help you get the most out of  $\LaTeX$  for your writing process.

## 5.1 Never Use $\TeX$ primitives

In plain  $\TeX$ , writing a document involved a lot of manual adjustments and small programming tasks. With  $\LaTeX$ , virtually all of this work has already been done for you. Sophisticated document classes and packages automatically do a lot of work for you and you can tweak them through a well documented user interface. Do that! Don't try to reinvent the wheel.

$\LaTeX$  with its thousands of packages has a macro for everything! Even when you think the plain  $\TeX$  version seems to do the same thing (Why not use `\bf`, it does the same thing as `\bfseries` and is shorter, right?), don't (Well, it doesn't. `\bfseries` is better and you should *never* use `\bf!`).

The one exception many people make and that you will find in most code examples online is the way to switch to and from inline math. The  $\LaTeX$  way is to use `\(` and `\)`, the  $\TeX$  way is to use `$` for both. The reason for this exception is that they are functionally equivalent and people prefer typing one character over typing two. (Also, some people claim that the source is much more readable because `\(` and `\)` disappear in the text much more easily than `$`, but I would argue that that is not true in the age of code highlighting and a non-issue anyways, provided you use enough spaces in math mode.) So, what are the advantages of using `\(` and `\)`?

- It is consistent. You use  $\LaTeX$  syntax and avoid  $\TeX$  syntax for everything else, right?
- There is a different command for entering math mode than for exiting it. This also means clearer error messages when you have a math shift too many or too few.
- `\(` and `\)` are macros. This means that you can easily modify them to do additional things like, say, draw a box around each inline formula or print them in a different color. Try modifying `$`!

So, I recommend going the  $\LaTeX$  way, but I won't hit you if you don't.

## 5.2 Use Macros and Use Them Semantically

Don't be afraid to write simple macros! Have a lot of street names in your text and you aren't sure if you want to use a different font for those? Write a macro `\street` (it doesn't have to do anything right now). You have names of clubs and city offices and you want to print both of them in slanted font? Write two macros `\club` and `\office`. Have names or values in your text that are subject to change? Make them macros.

---

<sup>11</sup><https://git-scm.com/>

So, create new macros liberally and remember that it is important to name them semantically: The name of the macro should reflect what it *means*, what it *represents* and not how it will affect the output. Macros that have the same effect on their arguments but represent different things should have different names. This makes the document source more understandable to future readers, makes the macro names easy to remember as you write your document and enables you to easily change the formatting of just one thing and leave others unaffected.

As an example, the `\times` macro prints the symbol  $\times$  in math mode. I prefer to use the symbol  $\cdot$  that can be created with `\cdot` for multiplication. Now, many people just write `\cdot` instead of `\times`, but it is better to change the definition so that `\times` produces  $\cdot$ . You can store the original definition of `\times` in a different macro, say `\xtimes` or `\vectimes`, depending on how you plan on using it.

Another example is the notation of vectors. By default, `\vec{s}` prints  $\vec{s}$ , but I prefer bold symbols instead of the arrow to denote vectors. So, I change the definition of `\vec` so that `\vec{s}` now prints  $\boldsymbol{s}$ .

## 6 Taking Care of Spaces

### 6.1 Normal and End-of-Sentence Spaces

In some languages, including English, spaces between sentences are commonly printed wider than normal inter-word spaces. (Carefully look at the spaces in this document for an example.) T<sub>E</sub>X tries to detect which spaces are end-of-sentence spaces, but of course that is not entirely trivial. Every period is taken to be the end of a sentence, unless it is preceded by an uppercase letter. While this rule gets most cases right, sometimes you have to correct it.

- If the sentence ends with a capital letter, you have to add `\@` before the period

I live in the US`\@`. I was not born there, though.

- If the period is not the end of the sentence, you can

- add `\@` after the period

Miller et al.`\@` solved the problem.

or

- manually insert a normal space after the period using `\`

Miller et al.`\` solved the problem.

Most times this happens, the period denotes an abbreviation and you don't want a line break to follow it (cf. section 6.2). In those cases, you can

- insert a non-breaking space after the period using `~`

The group is abelian, i.e.`~`commutative.

Exclamation points and question marks show the same behavior as periods. Colons, semicolons and commas, too, though to a lesser extent.

If you don't want end-of-sentence spaces to be different from normal inter-word spaces, you can remove this effect with `\frenchspacing`. For many languages, including German,

this is the default. If you write in one of those languages or explicitly use `\frenchspacing`, you don't *have* to pay attention to all of this, but if you sometimes need it, I would recommend always doing it as a matter of good practice.

## 6.2 Using Non-Breaking Spaces

Sometimes, you don't want a line break to occur between two words. In those cases, you have to insert a non-breaking space instead of a normal one between the two words. In  $\text{\LaTeX}$ , this can be done using a tilde (`~`). The most common use cases for this are:

- Between words and numbers, e.g.
  - ◊ `room~101`
  - ◊ `72076~Tübingen`
  - ◊ `section~\ref{sec:example}`
  - ◊ The number `~\(\pi\)` has a value of about `~\((3\)`.
- In front of citations or short explanatory parenthesis and symbols, e.g.
  - ◊ Leslie Lamport is the author of `\LaTeX~\cite{lamport1994latex}`
  - ◊ Have you been to the United States of America~(USA)?
  - ◊ The entropy~`\(S\)` of a system never declines.
- After many common abbreviations, e.g.
  - ◊ Many metals are superconductors, e.g.~Niobium and Aluminium.
  - ◊ Don't be stupid, i.e.~use `\LaTeX`, not Word!
  - ◊ Mr~and Mrs~Smith

There are, of course, more situations where the use of a non-breaking space is appropriate. Make a habit of always using a non-breaking space in these cases.

## 6.3 Avoiding Spurious Spaces

As mentioned in section 4.5, a single newline is treated by  $\text{\TeX}$  like a space. When you want to break some content over several lines in the source for readability and clarity, but not insert spaces between the lines, you need to comment the newline.

```
\colorsquare{red}
\colorsquare{blue}

\colorsquare{red}%
\colorsquare{blue}
```

If the last token in a line is a control word, the newline character is gobbled, just like a space, so you don't have to comment it.

```
\redsquare  
\bluesquare
```

## 7 Using the Correct Dash

There are four different dashes that regularly occur in texts:

- The hyphen (German *Bindestrich*) created using -: “-”  
This dash is used to connect words as in “non-breaking space”.
- The en-dash (German *Halbgeviertstrich*) which is created using --: “–”  
It has many uses, most notably ranges (“There may be 2 – 5 people per room.”) and, in German writing, separating some statement from the surrounding sentence (German *Gedankenstrich*; “Es gibt viele Anwendungen – wie dieser Satz beispielhaft zeigt – für den Halbgeviertstrich.”). In English writing (*not* in German), it is also used as a substitute for the hyphen when two names belonging to different persons are to be connected, as in “Ginzburg–Landau theory”.
- The em-dash (German *Geviertstrich*) which is created using ---: “—”  
It isn’t really used at all in German texts, but in English writing it serves many of the purposes the en-dash does in German.
- The minus sign, which is created using - in math-mode: “-”  
Obviously, this is used to denote subtraction as well as negative numbers (“ $5 - 7 = -2$ ”).

For comparison, here are all of them next to each other: - – — —.

Depending on the font used, these dashes may differ (apart from width) in thickness, vertical position and shape. Make sure to always use the correct dash for your application! The wrong dash will look hideous and impede reading your text.

## 8 Writing Clean Source Files

While many aspects of the formatting of your source file do not affect the compiled document, it is still advisable to keep it clean and easy to read. This helps you stay in control of your whole document while writing and is especially important if you or anyone else is to look at that file later on. Here are some guidelines you should follow in order to prevent your source from becoming an utter mess.

### 8.1 Write One Sentence per Line

For this to work, you will have to disable automatic line wrapping in your editor, which I would recommend anyway, because a changing appearance of your text with changing window sizes is confusing. Following this guideline has many advantages.

- The number of sentences per paragraph is obvious.

- The (approximate) length of sentences is immediately apparent. This is especially useful if you tend to sometimes write very long sentences (German *Bandwurmsatz*). You can quickly spot them as lines that are much longer than most.
- Consecutive sentences starting with the same word(s) are easily detected, as equal words right above each other catch the eye.
- The fact that all sentence endings are at the end of a line makes it much easier to search for periods that do not mark the end of a sentence. This may be relevant for the spacing inserted by  $\text{T}_{\text{E}}\text{X}$  (cf. section 6.1).

Note that I diverge from this guideline in some code examples in this document. This is owed solely to the space restrictions of a page and should not be taken as something to emulate in a real  $\text{TEX}$  file.

## 8.2 Choose Clear Label Names

When labeling document elements (using `\label`), the label name you choose should be something clearly identifying the object it refers to. Ideally, you should be able to remember the name of anything you want to reference. You should certainly be able to remember what a label refers to when reading its name.

In order to achieve this, it is useful to follow the following naming convention.

- Every label consists of two parts. First, the type of element it refers to, and second, a description of the element, separated by a colon:  $\langle type \rangle : \langle description \rangle$
- The  $\langle type \rangle$  is a shortened form of the thing you are labeling. For example, I use `chap` for chapters, `sec` for sections, subsections and subsubsections, `fig` for figures, `tab` for tables and `eq` for equations.
- The  $\langle description \rangle$  consists of letters and hyphens and is verbose enough to clearly identify the object. I usually don't abbreviate words in the  $\langle description \rangle$ .

For example, this section (8.2) has the label `sec:label-clearly` and section 12.4 has the label `sec:number-unit-macros`. Figure 1 on page 47 has the label `fig:tex-lion` and table 1 on page 48 has the label `tab:natural-constants`. Even without looking at the objects I just referenced, you can probably guess what you will find there, which is exactly the point.

## 8.3 Liberally Use Spaces in Math Mode

Math expressions often consist of mainly macros and single letters. Since spaces in math mode do not affect the output, you could theoretically live without using any spaces there. This will however lead to a terrible mess nobody wants to read. It is much better to liberally use spaces. Insert single spaces between every element of the math expression (variables, operators, etc.) that do not form a unit (the exponent should be attached directly to its base). When the expression gets really long, it may be useful to break it across lines. Try and find out what helps, go with more spaces when in doubt.

```

\(\sqrt{ab}\leq\frac{a+b}{2}\) is way worse than
\(\sqrt{a\ b}\ \leq\ \frac{a\ +\ b}{2}\)
and
\[
\frac{n}{\sum_{i=1}^n\frac{1}{a_i}}=\sqrt{\sum_{i=1}^na_i^2}\quad\text{iff}
\quad a_i=a_j\;;\;\text{forall}\;;\;i,j\in\{1,\dots,n\}
\]
is way worse than
\[
\frac{n}{\sum_{i=1}^n\frac{1}{a_i}}=\sqrt{\sum_{i=1}^na_i^2}
\quad\text{iff}\quad
a_i=a_j\;;\;\text{forall}\;;\;i,j\in\{1,\dots,n\}\ .
\]

```

$\sqrt{ab} \leq \frac{a+b}{2}$  is way worse than  $\sqrt{ab} \leq \frac{a+b}{2}$  and

$$\frac{n}{\sum_{i=1}^n \frac{1}{a_i}} = \sqrt{\sum_{i=1}^n a_i^2} \iff a_i = a_j \forall i, j \in \{1, \dots, n\}$$

is way worse than

$$\frac{n}{\sum_{i=1}^n \frac{1}{a_i}} = \sqrt{\sum_{i=1}^n a_i^2} \iff a_i = a_j \forall i, j \in \{1, \dots, n\}.$$

## 9 Avoiding Typographical Sins

While  $\text{\LaTeX}$  makes it pretty hard to make certain typographical mistakes, especially regarding consistent formatting, there are still some errors regularly made by inexperienced users. We already mentioned spaces and dashes. Here are some guidelines to help you avoid other issues.

### 9.1 Trust the Defaults

$\text{\LaTeX}$  and its packages usually have pretty good defaults set for all options. If you know what you are doing or you have to follow some requirements, e.g. from your school, go ahead and change them. But if something just feels different than in some other typesetting software, it's usually better to leave it be. When you are finished writing your document, you can still think about changing these options in the preamble, if necessary.

Page margins are a typical example for this. KOMA-Script has default margins that many new users perceive to be rather large. This is on purpose and actually common in good typography. In fact, the KOMA-Script manual explains this default in some length. If

your school forces you to use some horrible settings like 2 cm of margin on each side, fine. Otherwise, just let it be. If you still want to reduce the margin, using KOMA-Script options (like DIV or maybe `\areaset`) is usually much preferable to a crude totally manual definition.

## 9.2 Never Use Manual Line Breaks

When writing text, you should let  $\text{\TeX}$  do the line breaking for you.  $\text{\TeX}$  works very hard to break your paragraphs into lines nicely and usually succeeds in doing so. If you get a bad line break (a word sticks out or the spaces get stretched a lot), then there is probably no good way of breaking that line. The best way to deal with that is usually to rephrase the sentence in question.

Note that I am breaking this rule in some of the code examples in this document. This is purely to conserve space (an empty line would take up more) and should not be taken as something to emulate (the examples in question would not appear like that in a real document).

## 9.3 Never Use Manual Page Breaks

The reasoning of the previous section applies analogously.

## 9.4 Avoid Widows and Orphans

When a page break occurs right before the last line of a paragraph, this line appears isolated at the top of the next page. This is called a *widow* (German *Hurenkind*). The opposite case, when a page break occurs right after the first line of a paragraph and leaves that line isolated at the bottom of the page, is called an *orphan* (German *Schusterjunge*). Both of these should absolutely be avoided.

Luckily, this is rather easy in  $\text{\LaTeX}$  using the `nowidow` package as described below in section 11.1.

## 9.5 Don't Make Your Tables Ugly

Inexperienced users often try to recreate the look of tables they are used from other typesetting software in  $\text{\LaTeX}$ , emulating inadequate layouts. This leads to results like this.

Branch	Language	Word for Bread	Word for Water
Germanic	English	bread	water
	German	Brot	Wasser
	Norwegian	brød	vann
Romance	Spanish	pan	agua
	French	pain	eau
Finno-Ugric	Estonian	leib	vesi
Slavic	Slovak	chlieb	voda

There are many bad things about this table. The main one is that there are way too many lines. They make the table considerably less comprehensive. Don't do that, don't imprison your data [data-prison]<sup>12</sup>!

The booktabs package helps produce beautiful, comprehensive tables. Since it cannot be said often enough, I will quote the two most important guidelines listed in its documentation:

1. Never, ever use vertical rules.
2. Never use double rules.

For some examples of how to write good tables, see section 12.12.

## 9.6 Let Floats Float

Documents usually consist mainly of text. Since the height of a line of text is much smaller than the height of the type area, it is typically not too difficult to break the document into pages at reasonable positions. However, there are some objects regularly appearing in documents that are much larger than a line of text, namely figures and tables. When just inserted in the text, they often necessitate very early page breaks leading to underfull pages or leave only one or two lines between, say, the image and the page border, which is not satisfying at all.

To solve this problem,  $\text{\LaTeX}$  uses so-called floats. Basically, you can tell  $\text{\LaTeX}$  to “take this box and place it wherever”, the box is allowed to “float” around your document. Every such object then receives a caption describing its content and a number which can be used to refer to it in the text of the document. The environments `figure` and `table` are intended for this purpose and explained in section 12.14.

New users often feel uncomfortable with letting  $\text{\LaTeX}$  decide where to place their figures and tables and constantly tell  $\text{\LaTeX}$  to place the float where they placed it in the source file (using the optional argument of the float environment). Of course, this completely defeats the purpose of the environment. Let go of the fear that it will end up in some inconvenient place (that will change anytime you modify your document, anyway) and just let it float (i.e. don't use the optional argument). At the very end, when everything else is done and you are checking your document for possible cosmetic improvements, some adjustments can be made, though placing the float “here” (where it is in the source) really never is the best option.

If you really, *really* want some figure or table to exactly be at some place in the document, just don't put it into a float environment. A `center` environment is totally sufficient. In these cases, a caption and number are probably not necessary, but they can of course still be added. I can, however, only stress that this is virtually never the way to go in scientific and technical writing.

## 9.7 Cleanly Separate Text and Math Mode

Math mode and text mode are fundamentally different in a number of ways. Sometimes the differences in output are rather subtle in specific cases, sometimes there may be none at

<sup>12</sup><https://betterposters.blogspot.com/2012/08/the-data-prison.html>

all. Still, especially because of the cases where the differences are subtle, it is important to cleanly separate math and text mode in the source.

Let us look at some examples.

```
\enquote{\(a, b, c\) and \(d\) are real numbers.} is wrong.\\
\enquote{\(a\), \(b\), \(c\) and \(d\) are real numbers.} is right.
```

“ $a, b, c$  and  $d$  are real numbers.” is wrong.

“ $a, b, c$  and  $d$  are real numbers.” is right.

Naturally, there are numbers that should be in text mode, like dates and years, but when a number is really part of a math expression, it should be in math mode even if there is no other math adjacent to it.

```
Leibniz published his calculus in~1684.
The variable~\(a\) has a value of~\((3)\).
```

Leibniz published his calculus in 1684. The variable  $a$  has a value of 3.

Of course, numerical values, at least those that are not small integers (say, up to four digits), should be typeset using `siunitx` (see section 12.4). This conveniently eliminates the need to switch to or from math mode, since the `siunitx` macros behave identically in both. This is especially important when a decimal marker is involved.

```
\enquote{The golden ratio has a value of about~\((1.618\)).} is bad.\\
\selectlanguage{ngerman}\sisetup{locale=DE}%
\enquote{Der Goldene Schnitt beträgt etwa~\((1,618\)).} ist total falsch.\\
\enquote{Der Goldene Schnitt beträgt etwa~\num{1.618}.} ist richtig.
```

“The golden ratio has a value of about 1.618.” is bad.

„Der Goldene Schnitt beträgt etwa 1,618.“ ist total falsch.

„Der Goldene Schnitt beträgt etwa 1,618.“ ist richtig.

The converse case, where you want to write text in math mode, is to be treated analogously.

```
\[
  C(n) = \begin{cases}
    \frac{n}{2} & \text{if } (n) \text{ is even} \\
    3n + 1 & \text{if } (n) \text{ is odd}
  \end{cases}
\]
```

$$C(n) = \begin{cases} \frac{n}{2} & \text{if } n \text{ is even} \\ 3n + 1 & \text{if } n \text{ is odd} \end{cases}$$

## 9.8 Use the Correct Math Font

Normally, when you write a letter in math mode, it is typeset as a variable, i.e. in italic font without italic correction. Thus,  $v_0l$  in math mode means “the variable  $v$  times the variable  $o$  times the variable  $l$ ” and not “the variable  $v_0l$ ” or anything of the sort. Besides plain readability (cf. section 8.3), this is a good reason to write  $v \circ l$  instead of  $v_0l$ .

When you don’t actually mean the product mentioned above, as is often the case in indices, you need to switch to the upright (*roman*) font using `\mathrm{⟨expression⟩}`.

`\(W_{Vol}\)` is hideous and wrong. `\(W_{\mathrm{Vol}}\)` is right.

$W_{Vol}$  is hideous and wrong.  
 $W_{\mathrm{Vol}}$  is right.

This is true for single letter indices, too, of course. Whenever you use an index, you should be clear on if it denotes a variable, like the  $n$ -th Fibonacci number  $f_n$  or the  $z$ -component of the magnetic field  $B_z$ , it should be typeset as such, i.e. in the default math font. When the index denotes the name of a variable, i.e. it indicates a word rather than a variable, then it should be typeset using `\mathrm`, like the Boltzmann constant  $k_B$  or the critical temperature  $T_c$ .

This is to be distinguished from actual text in math mode, which was discussed in the previous section.

## 9.9 Manually Add Space in Math Mode When Helpful

Similarly to how spaces can help make math source code more readable (cf. section 8.3), adding additional spaces to the math output can make an expression, especially long ones, more easily readable. Adding small spaces or explicit multiplication signs can go a long way sometimes. The macros you can use for this are listed in section 12.7. Usually `\,` is enough, though. Here are some examples.

```
\begin{align*}
\psi &= \sqrt{n_{\mathrm s}} \, \, \, \mathrm{e}^{\mathrm{i} \, \varphi} & \text{rather than} & \& \\
\psi &= \sqrt{n_{\mathrm s}} \, \mathrm{e}^{\mathrm{i} \, \varphi} & & \\
\dot{\delta} &= \frac{2 \, \pi}{\Phi_0} \, \, \, U & \text{rather than} & \& \\
\dot{\delta} &= \frac{2 \, \pi}{\Phi_0} \, U & & \\
\beta_C &= \frac{2 - (\pi - 2)}{i_{\mathrm r} \{ i_{\mathrm r}^2 \}} & \text{rather than} & \& \\
\beta_C &= \frac{2 - (\pi - 2)}{i_{\mathrm r} \{ i_{\mathrm r}^2 \}} & & \\
v_{\mathrm{ph}} &= \mathrm{num}\{0.415(18)\} \, \, \, c & \text{rather than} & \& \end{align*}
```

<pre>v_{\mathrm{ph}} &amp;= \num{0.415(18)} c \end{align*}</pre>		
$\psi = \sqrt{n_s} e^{i\varphi}$	rather than	$\psi = \sqrt{n_s} e^{i\varphi}$
$\delta = \frac{2\pi}{\Phi_0} U$	rather than	$\delta = \frac{2\pi}{\Phi_0} U$
$\beta_C = \frac{2 - (\pi - 2) i_r}{i_r^2}$	rather than	$\beta_C = \frac{2 - (\pi - 2) i_r}{i_r^2}$
$v_{\text{ph}} = 0.415(18) c$	rather than	$v_{\text{ph}} = 0.415(18) c$

In longer expression, a multiplication dot (which comes with extra spaces) is often better than just a small space.

The decision to insert a space or not is often rather subjective, however, and depends somewhat on the font you use. The main thing you should take away from this is that it is okay, even encouraged to manually insert spaces in math mode when they improve readability. Whenever you look at some math expression you wrote and think that some part of it is kind of hard to read, consider adding a space or more to remedy that.

## 10 Document Classes

### 10.1 The Base Classes

There are three base document classes included in any  $\text{\LaTeX}$  installation: `article`, `report` and `book`. They differ in a couple of default layout settings. The most important difference between them, however, is the sectioning commands they provide.

- `article` provides `\section`, `\subsection` and `\subsubsection` as well as `\paragraph` and `\subparagraph`. The latter two are not needed very often, though.
- `report` additionally provides `\chapter` (above `\section`).
- `book` additionally provides `\part` (above `\chapter`).

Accordingly, `article` is for short documents with closely related sections (e.g. papers, summaries or references), while `report` is for medium length documents with topically separated chapters (e.g. academic theses) and `book` is for long documents that need to be divided into even larger parts.

Use these differences to choose the right document class for your project. If you find yourself wanting to dramatically change the appearance of the headings (say you are using `article` and want every section to start on a new page or you need a `\subsubsubsection`) then you are probably using the wrong document class (just use `report`'s sectioning commands from `\chapter` to `\subsubsection` instead).

## 10.2 KOMA-Script

While the three base classes provide some descent default configuration, they do not expose a lot of the layout decisions to the user in the form of options and commands. Many authors will wish to change these defaults, especially since the preset adheres to an American typographical tradition and differs somewhat from European customs. In order to perform adjustments, the user has to either directly modify the internal macros of the document classes or load packages that do just that.

The KOMA-Script bundle offers an alternative approach. It provides the document classes `scrartcl`, `scrreprt` and `scrbook` as replacements for the base classes. These have the same general properties as the respective base classes with some slightly different default layout choices, but they provide a multitude of options and commands to modify the appearance of the document and conveniently access additional functionality. Using KOMA-Script, one should not be needing any further packages to modify the general appearance of the document (type area, headers and footers, section headings, etc.). As a bonus, the default settings are somewhat more satisfying to the European eye (KOMA-Script's author is German) which means less necessity for adjustments in many cases.

The bundle also contains some additional document classes (most notably `scrlettr2` for writing letters) as well as packages (most notably `scrlayer-scrpage`) that can be used with the KOMA-Script classes as well as different ones. Though studying the entire extensive manual [koma-script] is not necessary, chapters 2, 3 and 5 are probably a good read for any author using KOMA-Script.

## 10.3 Other Document Classes

There are, of course, many more document classes to choose from. I want to mention only some of them here.

- `memoir` is a document class that aims to replace all three base classes at once (mostly report and book, though) with many more options. While I have personally never used it and, accordingly, can't help with questions regarding it, it is certainly a large improvement to the base classes.
- `moderncv` is a document class for writing curricula vitae with a pretty slick look. Sadly, it does not have a manual (yet), but it comes with some examples one can use to get started.
- `beamer` lets you create presentations using  $\LaTeX$ . It is based on `TikZ`.

## 11 Packages

In the decades since the inception of  $\LaTeX$ , thousands of authors have written macros for all kinds of tasks and published them in the form of packages. The place where all of the public

packages are collected is the *Comprehensive TeX Archive Network*<sup>13</sup> (CTAN). Both MiKTeX and TeX Live include most of them, but you can also easily install additional packages manually.

You will, of course, never need most of these. I will give an incomplete list of frequently used ones here. If you want to do something more complex than simple text formatting that is not covered by these packages, ask your local L<sup>A</sup>T<sub>E</sub>X sage and search online before attempting to write the macro yourself. Chances are, there is a package for that.

### 11.1 Always Include These

If you are compiling with pdfL<sup>A</sup>T<sub>E</sub>X, you should always load the following packages.

- fontenc with the font encoding T1.

```
\usepackage[T1]{fontenc}
```

- textcomp, which provides access to additional glyphs in text mode. Importantly, `\textmu` (“μ”), which is needed for typesetting units such as μm, is only available after loading textcomp.
- Depending on the PDF viewer, there may be some issues with copying or searching through text with ligatures. This can be remedied by adding the following lines to the preamble:

```
\input{glyphtounicode}
\pdfgentounicode=1
```

- After selecting the T1 font encoding, you need to load a compatible font. If you just want to use the default font (it is a good font), load lmodern. If you want to select a different one, see section 11.3.

When compiling with LuaL<sup>A</sup>T<sub>E</sub>X (or XeL<sup>A</sup>T<sub>E</sub>X), these packages are not necessary. In fact, you will get errors if you try to load them with those engines.

Irrespective of the engine you are using, you should also always load the following packages.

- babel for localization. This package provides language selecting and switching capabilities and, depending on the language, defines some useful shorthands. You should always give the main language of your document as an option to your document class, not only to babel. This will ensure that other packages that care about the language also get it. You really only need to tell babel directly about document languages if there are more than one.
- microtype; the documentation’s subtitle really says it all: *Subliminal refinements towards typographical perfection*. Just load it, you don’t have to do anything more, and your document will be prettier with many fewer bad boxes.

<sup>13</sup><https://ctan.org/>

- nowidow to avoid widows and orphans (cf. section 9.4). It allows you to select how many lines of a paragraph  $\text{\TeX}$  has to keep together when breaking it across pages. I usually load it with the following options:

```
\usepackage[defaultlines=2, all]{nowidow}
```

## 11.2 Programming

For modifying or writing your own macros, the following packages are often helpful.

- etoolbox is a collection of useful wrapper macros to take advantage of the  $\epsilon\text{-}\text{\TeX}$  primitives.
- xparse provides an advanced argument parser, i.e. it makes it way easier to define macros with all kinds of arguments, e.g. mandatory, optional and star arguments.

## 11.3 Font Selection

### 11.3.1 With pdf $\text{\LaTeX}$

Because  $\text{\LaTeX}$  is old, older than formats like TTF or OTF, you cannot just load a system font like in other software. The process of preparing a font for use in  $\text{\LaTeX}$  is a bit involved, so it's better to stay out of that and stick with the fonts that other people prepared for you. If you really want to use one of your system fonts, use Lua $\text{\LaTeX}$  instead (see below).

The default  $\text{\TeX}$  font, designed by Knuth himself, is called Computer Modern, its T1 clone is called Latin Modern and available via the package lmodern. It is a very good font for scientific and technical writing, especially because it contains all the important math fonts. If you don't really care about your document's font, just stick with this one.

*The  $\text{\LaTeX}$  Font Catalogue*<sup>14</sup> lists fonts available in  $\text{\LaTeX}$  organized into categories with text examples. Have a look and pick a font you like, but keep in mind that you should pick one with math support if you use any math. This document uses the STIX 2 fonts, available through the stix2 package.

### 11.3.2 With Lua $\text{\LaTeX}$

With Lua $\text{\LaTeX}$  (or Xe $\text{\LaTeX}$ ), you have the possibility to load OTF fonts, so you pretty much use any font you have installed on your machine or for which you can find an OTF file. The interface for this is provided by the fontspec package for text and unicode-math for math fonts. I recommend loading unicode-math with the math-style=ISO option.

```
\usepackage[math-style=ISO]{unicode-math}
```

<sup>14</sup><https://tug.org/FontCatalogue/>

Keep in mind that, if you need math expressions, your math font should match your text font. Since choosing fonts is hard, I recommend sticking with math and text fonts that come together. Again, *The L<sup>A</sup>T<sub>E</sub>X Font Catalogue* is a great resource.

Many fonts are still available as packages that load the desired fonts using the appropriate packages and options. For example, you can still load the STIX 2 fonts using the package `stix2`. It will detect the use of LuaL<sup>A</sup>T<sub>E</sub>X and internally load `stix2-otf` instead of `stix2-type1` in order to set up the fonts.

## 11.4 Text

- `xcolor` provides extended color handling capabilities. If you want to use colors, load it.
- `hyperref` is for creating hyperlinks, inside of your document as well as to other files or websites. Just loading it turns all internal references in your document to hyperlinks. I usually load it with the `hidelinks` option in order to suppress the box that is displayed around links by default.

With very few exceptions, `hyperref` should be the *last* package you load!

- `array` gives you an improved version of L<sup>A</sup>T<sub>E</sub>X's `tabular` and `array` environments. If you have any of those, load it.
- `booktabs` provides the commands needed to create beautiful tables (cf. section 9.5).
- `enumitem` extends the list environments with many useful options and lets you easily define new or modify the default ones.
- `siunitx` is the package for typesetting numbers and units. If you only ever need integers below 1000 and not units, you're fine. Otherwise, use this package! You should specify a typographic convention using the `locale` option.

```
\usepackage[locale=DE]{siunitx}
```

- `mhchem` lets you easily typeset chemical formulas. You have to specify a version when including it, at the time of writing the current version is 4.

```
\usepackage[version=4]{mhchem}
```

- `csquotes` provides context sensitive quotation commands. Whenever you want to set anything in quotation marks, use this package.
- `biblatex` is the package to use for citations and bibliographies. Do *not* use B<sub>B</sub>T<sub>E</sub>X, `biblatex`'s predecessor; it is outdated and deprecated.
- `glossaries` and its extension `glossaries-extra` can be used to create glossaries. Sadly, its documentation can be a bit confusing and it can be hard to find what you are looking for, but it is unrivaled in functionality.

- `acro` is a slim alternative to glossaries for the case of simple lists of acronyms. For English texts, this may be the better choice if you are unfamiliar with glossaries.

If you are writing in German, everything gets much more complicated due to declension. I created a system to handle this using `glossaries-extra` for my master's thesis, but it's a bit involved. If you are using a lot of abbreviations in a German document and are interested in this, I can show you though.

- `verbatim` provides an improved reimplementation of  $\text{\LaTeX}$ 's `verbatim` and `verbatim*` environments. If you need these, load it.

## 11.5 Graphics Inclusion and Creation

$\text{pdf}\text{\LaTeX}$  can include images in the PDF, PNG and JPG formats. SVG files can also be conveniently included via the PDF route with the added feature of  $\text{\LaTeX}$  typesetting the text portion of the drawing. Furthermore, you can create vector drawings yourself directly with  $\text{\LaTeX}$ .

Here's the packages you should be aware of for this:

- `graphicx` enhances  $\text{\LaTeX}$ 's native graphics inclusion capabilities. Whenever you want to include an image, load this package.
- `svg` provides a system to automatically export SVG drawings to PDF and TEX files using Inkscape and include those in your document.
- `tikz` (stylized as `TikZ`) is a simple but powerful interface for creating drawings with  $\text{\LaTeX}$ . It is the basis for many other packages that create any kind of drawing. Its back end is called PGF.
- `tcolorbox` is the package to go to for creating (colored) boxes. This is also useful for creating posters in  $\text{\LaTeX}$ .

## 11.6 Mathematics

Some of the packages mentioned above also affect math mode macros and environments (e.g. `array`) or provide commands that can be used both in text and in math mode (e.g. `siunitx`). Additionally to those, the following packages are often used.

- `amsmath` (by the American Mathematical Society,  $\mathcal{AMS}$ ) brings many enhancements to standard math typesetting. You should load it (or `mathtools`, see below) whenever you have any math content in your document. (Other packages from the  $\mathcal{AMS}$  family, like `amssymb` and `amsthm`, may also be useful.)
- `mathtools` further enhances `amsmath` and standard  $\text{\LaTeX}$  capabilities. It automatically loads `amsmath`, so you don't have to do it if you use `mathtools` (and don't want to pass any options to `amsmath`).
- `bm` (for *bold math*) provides access to bold math symbols. There are other ways to get bold math, but I recommend this one.

- `dsfont` gives you access to double stroke (*blackboard*) math letters (like “ $\mathbb{Z}$ ”) when using `pdfLATEX`.

## 11.7 Code Listings

If you need to print source code listings, like I regularly do in this document, and you want capabilities exceeding those of the `verbatim` environment (like syntax highlighting or line numbers), there are two packages you may choose from.

- `listings` is a syntax highlighter implemented purely in `LATEX`. It requires no setup besides loading the package and its functionality is sophisticated enough for most simple codes listing needs. For obscure languages, you will have to define the highlighting scheme yourself, which is rather easy, though. For more advanced highlighting schemes, however, you may find certain limitations.
- `minted` uses *Python*’s<sup>15</sup> powerful *Pygments*<sup>16</sup> library for syntax highlighting, with over 500 languages and many color schemes predefined. This means a bit more setup, as you need to install Python with Pygments and enable `shell-escape`, but it can handle more edge cases and may more easily give you the desired results if you are already familiar with Python and Pygments.

## 11.8 Other

- `geometry` lets you explicitly set the measures defining the page layout. Especially when using KOMA-Script, you should not do this! It is really only okay when you have to follow rules that demand a bad layout (e.g. 2 cm border on all sides).
- `scrlayer-scrpage` belongs to the KOMA-Script bundle and allows you to set up complex page layouts. Most of the time, you only want to modify the content of your page headers and footers, though.
- `pdflscape` allows you to rotate single pages of your document. In contrast to the `lscape` package it is based on, the pages appear rotated in PDF viewers.
- `rotating` allows you to rotate single objects. Most notably it provides the rotated floating environments `sidewaystable` and `sidewaysfigure`.
- `caption` is for customizing captions of floating environments. While KOMA-Script has those capabilities as well (and you should use the KOMA-Script options rather than the ones provided by `caption` when using both), you also want `caption`’s `hypcap` option. This option makes hyperlinks to, say, a figure point to the top of the figure instead of its caption. If you have any floating environments in your document, I recommend loading `caption` with this option.

<sup>15</sup><https://python.org/>

<sup>16</sup><https://pygments.org/>

```
\usepackage[hypcap]{caption}
```

This package should be loaded *after* hyperref!

- subcaption provides macros and environments for typesetting subfloats (e.g. subfigures) and plays well with caption (it is by the same author). Load this package after caption.

## 12 Important Macros and Environments

Here is a list of the macros and environments that you are likely to need when writing documents using  $\text{\LaTeX}$ . It is not complete in any way. If you feel that I left out any important ones, feel free to let me know.

### 12.1 Font Switching

The following macros are font switches, i.e. they change the font immediately until the end of the current group.

`\normalfont` switches to the document's default font.

`\rmfamily`, `\sffamily`, `\ttfamily` switch to the roman (serif), sans serif and typewriter font (monospace; German *dicktengleich*), respectively.

`\upshape`, `\itshape`, `\slshape`, `\scshape` switch to upright, italic, slanted and small capital letters, respectively.

`\mdseries`, `\bfseries`, `\lfseries` switch to normal (medium), bold and light font weight, respectively.

Note that many fonts do not support all (possible combinations) of these.

There are commands that take the text to be typeset as an argument for every one of these switches: `\textnormal`, `\textrm`, `\textsf`, `\texttt`, `\textup`, `\textit`, `\textsl`, `\textsc`, `\textmd`, `\textbf` and `\textlf`. These basically have the same effect as using a group with the appropriate switch at the beginning, but additionally take care of italic correction where appropriate.

```
King {\itshape George III} had a crown. \\
King \textit{George III} had a crown.
```

```
King George III had a crown.
King George III had a crown.
```

As a rule, it is better to use the `\textxx` commands when switching inside of a paragraph, usually for just a few words. When switching for whole paragraphs or the content of an environment, go with the switches.

Remember that you should not use these commands directly in your document, but only in definitions in your preamble (cf. section 5.2)! A very common use for switching fonts is to *emphasize* a word or phrase, which is usually done using the italic font.  $\text{\LaTeX}$  already provides a semantic command for that: `\emph{<text>}`. It is constructed such that it usually

switches to italic font, but instead switches to upright font if the surrounding text is already italic.

## 12.2 Counters and Numbering

$\text{\TeX}$  counters are used to, well, count things. They are basically like an integer variable in other programming languages and can take values ranging from  $-2^{31}$  to  $2^{31} - 1$ . You can manipulate them with the following macros.

`\newcounter{<name>}` creates a new counter called `<name>`. It initially has the value 0.

`\stepcounter{<name>}` increases the value of the counter `<name>` by 1.

`\setcounter{<name>}{<value>}` sets the value of the counter `<name>` to `<value>`.

All assignments performed by these macros are global, i.e. not confined to the current  $\text{\TeX}$  group!

Typical applications for counters are numbering sections, figures, or footnotes. The values of these document elements are stored in the counters `section`, `figure` and `footnote`. When these numbers are printed, you may desire a different format than just printing the Arabic digits. For this purpose, the following commands are provided.

`\arabic{<name>}` prints an Arabic numeral: 1, 2, 3, 4, 5, 6, 7, 8, 9

`\roman{<name>}` prints a lower case Roman numeral: i, ii, iii, iv, v, vi, vii, viii, ix

`\Roman{<name>}` prints an upper case Roman numeral: I, II, III, IV, V, VI, VII, VIII, IX

`\alph{<name>}` prints a lower case Latin letter: a, b, c, d, e, f, g, h, i

`\Alph{<name>}` prints an upper case Latin letter: A, B, C, D, E, F, G, H, I

`\fnsymbol{<name>}` prints one of nine footnote symbols: \*, †, ‡, §, ¶, ||, \*\*, ††, ‡‡

If you want to use the value of a counter at a place where  $\text{\TeX}$  expects a number, you can use `\value{<name>}`.

The formatting for the counter `foo` is usually stored in a macro called `\thefoo`. For example, the formatted section number is typeset by the macro `\thesection`. If you want to change that format, say you want capital letters, you can redefine this macro.

```
\renewcommand*\thesection{\Alph{section}}
```

For the format of page numbers the macro `\pagenumbering` is provided which changes the numbering format and additionally resets the page number to 1. So, if you want to change the page numbering to lower case Roman numerals starting at i, you just have to say

```
\pagenumbering{roman}
```

## 12.3 Sectioning

For sectioning, the commands `\part`, `\chapter`, `\section`, `\subsection`, `\subsubsection`, `\paragraph` and `\subparagraph` are provided, where `\part` is only available in book (or scrbook) and `\chapter` in report and book (scrreprt and scrbook). They differ in formatting and behavior, but their syntax is the same. We shall explain it using `\section`:

`\section[⟨short title⟩]{⟨title⟩}` creates a section heading with the title `⟨title⟩`. If the optional `⟨short title⟩` is given, it is used instead of `⟨title⟩` in the table of contents and for running titles.

Every sectioning level has a corresponding *depth value*, where sections have the depth 1. Accordingly, paragraphs have the depth 4 and parts have the depth -1. These depths are used to specify which sectioning levels should be numbered and which should appear in the table of contents using the following counters.

`secnumdepth` specifies the deepest sectioning level that should be numbered.

`tocdepth` specifies the deepest sectioning level that is to be included in the table of contents.

So, if you wanted to exclude everything below sections from the table of contents, you could set

```
\setcounter{tocdepth}{1}
```

## 12.4 Numbers and Units

Whenever you need to typeset numerical values other than just small integers, or when you need to typeset units, you should use `siunitx`! It provides the following commands (and some more handy shortcuts).

`\num[⟨options⟩]{⟨value⟩}` prints numbers.

<code>\num{1234567890.0987654321} \\</code>	1 234 567 890.098 765 432 1
<code>\num{-3.55e-12} \\</code>	$-3.55 \cdot 10^{-12}$
<code>\sisetup{locale=DE}</code>	
<code>\num{2.656624(13)e8} \\</code>	$2,656\,624(13) \cdot 10^8$
<code>\num[quotient-mode=fraction]{3/5} \\</code>	$\frac{3}{5}$
<code>\num[separate-uncertainty]{2.54(8)e-3}</code>	$(2,54 \pm 0,08) \cdot 10^{-3}$

`\si[⟨options⟩]{⟨unit⟩}` prints units.

<code>\si{\kilo\gram\meter\per\square\second} \\</code>	$\text{kg m s}^{-2}$
<code>\si[per-mode=fraction]</code>	
<code>  {\kilo\gram\square\meter</code>	$\frac{\text{kg m}^2}{\text{A s}^2}$
<code>  \per\ampere\per\square\second} \\</code>	
<code>\sisetup{per-mode=symbol}</code>	$\text{mJ}/(\text{A s})$
<code>\si{\milli\joule\per\ampere\per\second}</code>	

`\SI[⟨options⟩]{⟨value⟩}{⟨unit⟩}` prints a value with a unit.

```
\(\mu_0 = \SI{1.25663706212(19)e-6}{\newton\per\square\ampere}\),
furthermore, you should wait for pretty much exactly
\SI[separate-uncertainty]{8.77654(23)}{\nano\second}
before proceeding. By the way, my new room is
\SI{5x3}{\meter} large.
```

$\mu_0 = 1.256\,637\,062\,12(19) \cdot 10^{-6} \text{ N A}^{-2}$ , furthermore, you should wait for pretty much exactly  $(8.776\,54 \pm 0.000\,23) \text{ ns}$  before proceeding. By the way, my new room is  $5 \text{ m} \times 3 \text{ m}$  large.

`\ang[⟨options⟩]{⟨value⟩}` prints angles.

```
\ang{1.234} \\\
\ang{-3;5;8}      1.234°
                  -3°5'8''
```

As the format of numbers and units depends on the `siunitx` configuration, you may get a different output than in these examples. I loaded the package with the following options (replace  $\times$  by  $\cdot$ , use US locale, use  $\times$  when printing products):

```
\let\xtimes\times
\let\times\cdot
\usepackage[
  locale=US,
  output-product=\xtimes,
]{siunitx}
```

If you need any units that are not predefined by `siunitx` or want to define a shorthand for longer units, you can do so using `\DeclareSIUnit[⟨options⟩]{⟨unit⟩}{⟨symbol⟩}`.

```
\DeclareSIUnit\dBm{dBm}
```

For typesetting numeric values in tables, please see section 12.12.

## 12.5 Chemical Symbols

The `mhchem` package provides `\ce`, which can be used to easily typeset chemical formulas in both text and math mode.

```
The compound \ce{YBa2Cu3O_{7-x}}
is a high-temperature superconductor.
\[
\ce{C6H12O6 -> 2 C2H5OH + 2 CO2}
\]
```

The compound  $\text{YBa}_2\text{Cu}_3\text{O}_{7-x}$  is a high-temperature superconductor.

## 12.6 Display Math Environments

There are a number of display math environments and it is important to use the right one for the task at hand. All of the environments presented here are provided by `amsmath`, other display math environments present in  $\text{\LaTeX}$  2<sub>ε</sub> should not be used.

The following environments are intended to display single equations.

`equation` is the most basic one and displays one centered equation.

```
\begin{equation}
  a^b - b^a = 1
\end{equation}
```

$$a^b - b^a = 1 \quad (1)$$

`multline` is for equations that are too wide for one line. Use `\\` to insert line breaks. The first line in a `multline` will be left aligned, the last one right aligned and all the lines in between will be centered.

```
\begin{multline}
  0 = a + b + c + d + e + f + g + h + i + j + k + l + m + n + o \\
  + p + q + r + s + t + u + v + w + x + y + z
\end{multline}
```

$$0 = a + b + c + d + e + f + g + h + i + j + k + l + m + n + o \\ + p + q + r + s + t + u + v + w + x + y + z \quad (2)$$

For displaying multiple equations at once, the following environments can be used.

`gather` displays several equations (separated by `\\`[(*dimension*)]), each of them centered independently. As in `tabular`, the optional argument of `\\` can be used to sometimes insert extra (possibly negative) space between equations. The last equation must *not* be terminated with `\\`.

```
\begin{gather}
  a^p \equiv a \pmod{p} \\
  a^n + b^n \neq c^n
\end{gather}
```

$$a^p \equiv a \pmod{p} \quad (3)$$

$$a^n + b^n \neq c^n \quad (4)$$

`align` does the same, but you can specify alignment points using `&`. Think of this environment like a table with alternating `r` and `l` columns. Every pair of columns forms an equation, the equations are spaced out equally on the line. The `&` inside an equation must be placed *before* the character you want to align at, which should usually be a binary relation like `=`.

```
\begin{align}
a + b &= c &
c + e &= f \\\
g &= h + i &
j &= k + l \\
\end{align}
```

$$a + b = c \qquad c + e = f \qquad (5)$$

$$g = h + i \qquad j = k + l \qquad (6)$$

`alignat` is like `align`, but it takes the number of equations in one row as an argument and does not space out the equations horizontally, allowing you to specify that space yourself.

```
\begin{alignat}{2}
a + b &= c & \quad \quad \\
c + e &= f \\\
g &= h + i & \\
j &= k + l & \\
\end{alignat}
```

$$a + b = c \qquad c + e = f \qquad (7)$$

$$g = h + i \qquad j = k + l \qquad (8)$$

`flalign` is like `align`, but it spaces the equations out to the edges of the line.

```
\begin{flalign}
a + b &= c &
c + e &= f \\\
g &= h + i &
j &= k + l \\
\end{flalign}
```

$$a + b = c \qquad c + e = f \qquad (9)$$

$$g = h + i \qquad j = k + l \qquad (10)$$

There are starred variants of all of these environments that do the same thing, but with equation numbering turned off. The shortcut `\[ ... \]` is equivalent to the environment `\begin{equation*} ... \end{equation*}`.

Inside all of these environments, except for `multline` and `multline*`, the following may be used.

`split` is for single equations that need to be broken across several lines with alignment.

```
\begin{equation}
\begin{split}
0 = a &+ b + c + d + e + f + g + h + i + j + k + l + m + n + o \\\
&+ p + q + r + s + t + u + v + w + x + y + z \\
\end{split}
\end{equation}
```

$$0 = a + b + c + d + e + f + g + h + i + j + k + l + m + n + o + p + q + r + s + t + u + v + w + x + y + z \qquad (11)$$

`\tag{<text>}` may be used to manually specify the tag used for the current equation, either to replace the automatic equation number or to tag an equation that would otherwise be untagged.

`\notag` may be used to leave an equation untagged that would otherwise be tagged.

<pre>\begin{gather}   a + b = c \\   \tag{foo}   d + e = f \\   \notag   g + h = i \end{gather}</pre>	$a + b = c \quad (12)$ $d + e = f \quad (\text{foo})$ $g + h = i$
---	---

`\intertext{<text>}` may be used to insert text between two equations (without losing alignment). It may only be used directly following a `\\`.

`\shortintertext{<text>}`, provided by `mathtools`, is like `\intertext` but uses less vertical space. It is useful if the `<text>` to be inserted is just a few words long.

<pre>\begin{align}   a + b &amp;= c \\   \shortintertext{and also}   d &amp;= e + f . \end{align}</pre>	$a + b = c \quad (13)$ <p style="text-align: center;">and also</p> $d = e + f. \quad (14)$
---	--

Additionally, the following environments are available to be used in math mode. While they work in inline math mode, too, they are usually only appropriate in one of the environments listed above.

`cases` is for, well, listing different cases, as is commonly done in mathematics.

```
\begin{equation}\label{eq:little-fermat}
  a^{p-1} \bmod p
  = \begin{cases}
    0 & \text{if } (p \text{ divides } a) \\
    1 & \text{otherwise}
  \end{cases} \\
\end{equation}
```

$$a^{p-1} \bmod p = \begin{cases} 0 & \text{if } p \mid a \\ 1 & \text{otherwise} \end{cases} \quad (15)$$

`gathered`, `aligned` and `alignedat` are like the variants without `ed`, but for use inside the environments above. Their width is the natural width of their content as opposed to the full width of the line.

```

\begin{equation}
\left.
\begin{aligned}
(a + b)^2 &= a^2 + 2 a b + b^2 \\
(a - b)^2 &= a^2 - 2 a b + b^2 \\
(a + b)(a - b) &= a^2 - b^2
\end{aligned}
\right\}
\quad \text{\texttt{\text{leges binomiales}}}
\end{equation}

```

$$\left. \begin{aligned} (a + b)^2 &= a^2 + 2ab + b^2 \\ (a - b)^2 &= a^2 - 2ab + b^2 \\ (a + b)(a - b) &= a^2 - b^2 \end{aligned} \right\} \quad \text{leges binomiales} \quad (16)$$

In order to get an overview of the macros and environments available for mathematical typesetting, it is worthwhile to at least skim through the `amsmath` and `mathtools` documents.

## 12.7 Spaces in Math Mode

You can manually add spaces in math mode (cf. section 9.9) using the following macros.

`\,` adds a small math skip.  
`\:` adds a medium math skip.  
`\;` adds a thick math skip.  
`\quad` adds a skip of 1 em width.  
`\qquad` adds a skip of 2 em width.

## 12.8 Quotations

$\text{\LaTeX 2}_{\epsilon}$  comes with the following two basic quoting environments predefined.

`quote` indents the contained text on both sides. Paragraphs are separated by a vertical space.

`quotation` indents the contained text on both sides. First lines of paragraphs are indented.

These environments do not add any quotation marks to the text.

While it is of course possible to manually insert quotation marks in your text, you should never do that. Instead, use the capabilities of the `csquotes` package. It provides context sensitive quotation commands and environments, i.e. it automatically switches between outer and inner quotation marks and chooses the right ones for your language. The basic commands are `\enquote{<text>}` for regular quotations and `\foreignquote{<text>}` for quotations in foreign languages (using `babel`). With the package option `autostyle`, foreign language citations receive the quotation marks appropriate for their language.

```
\enquote{\enquote{I am English.}, said the man.} \\
\foreignquote{ngerman}{\enquote{Ich bin deutsch.} sagte der Mann.} \\
\foreignquote{spanish}{\enquote{Soy español.}, dijo el hombre.} \\
\foreignquote{norsk}{\enquote{Jeg er norsk.} sa mannen.}
```

```
“I am English.’, said the man.”
„Ich bin deutsch.’ sagte der Mann.“
«“Soy español.”, dijo el hombre.»
««Jeg er norsk.» sa mannen.»
```

The package provides a number of additional quotation commands and environments, like `\textquote`, `\blockquote` and `\displayquote`, as well as some auxiliary commands for ellipses, insertions and deletions (`\textelp`, `\textins`, `\textdel`). Have a look at the manual for details.

## 12.9 Verbatim Text

Sometimes, you want to print some text exactly as in the source file, without any macro expansion or other  $\text{T}_\text{E}\text{X}$  functionality. This verbatim output can be achieved with the following commands. The generated text is printed in typewriter font.

`\verb<char><content><char>` is for inline verbatim text. The `<char>` may be any character (well, almost, non-native characters like `ä`, `é` or `ß` won’t work) that does not appear in `<content>`. For example, `\verb|\foo{bar}|` prints “`\foo{bar}`”.

The starred version of this macro does the same thing, but it prints visible spaces, i.e. it outputs the character `␣` instead of a space. For example, `\verb|foo bar|` prints “`foo bar`”, but `\verb*|foo bar|` prints “`foo␣bar`”.

`verbatim` does the same but as an environment. Everything between `\begin{verbatim}` and `\end{verbatim}` is printed as is.

```
This is some normal text.
The usual \TeX\ rules apply.
\begin{verbatim}
This is verbatim text.
Normal \TeX\ rules do not apply.
\end{verbatim}
This is more normal text.
```

This is some normal text. The usual  $\text{T}_\text{E}\text{X}$  rules apply.

```
This is verbatim text.
Normal \TeX\ rules do not apply.

This is more normal text.
```

`verbatim*` does the same thing, but it prints visible spaces.

## 12.10 Footnotes

`\footnote[⟨number⟩]{⟨text⟩}` produces a footnote mark and places `⟨text⟩` as a footnote at the bottom of the page. If `⟨number⟩` is given it is used for the footnote mark, otherwise the counter `footnote` is incremented and used.

Sometimes it is useful or necessary to place the footnote mark and text separately. This way you can place footnotes in places where `\footnote` is not allowed, e.g. in tables. It may also be useful if you want to place several marks referring to the same footnote or if you just want to write the whole footnote in the middle of a sentence for clarity. This can be done with the following commands.

`\footnotemark[⟨number⟩]` produces only the mark.

`\footnotetext[⟨number⟩]{⟨text⟩}` produces only the footnote itself.

The format of the footnote mark is controlled by `\thefootnote`. If you want symbols (\*, †, ‡) instead of numbers (1, 2, 3), you can redefine it like this (cf. section 12.2):

```
\renewcommand*\thefootnote{\fnsymbol{footnote}}
```

## 12.11 Lists

There are three basic list types in  $\text{\LaTeX}$ .

`itemize` for bullet lists (items are labeled with symbols),

`enumerate` for enumerated lists (items are labeled with numbers) and

`description` for descriptive lists (items are labeled with text).

All of them use the same macro to indicate a new item.

`\item[⟨label⟩]` starts a new item and needs to be the first thing in any list. If `⟨label⟩` is given, it is used as the label, otherwise the default label is used (in `enumerate`, an appropriate counter is stepped first). Items in `description` lists should always use the optional argument.

Lists can be nested up to four levels deep. `itemize` and `enumerate` use different labels for every level. You can change the default labels by redefining the macros

- `\labelitemi` through `\labelitemiv` for `itemize`,
- `\theenumi` through `\theenumiv`, `\labelenumi` through `\labelenumiv` as well as `\p@enumi` through `\p@enumiv` for `enumerate` and
- `\descfont` for `description`.

If you want more control over the appearance of your lists, especially of the spacing, you should load the `enumitem` package. It provides commands for cloning and modifying the default lists and makes all the list environments accept an optional argument for changing these settings on an individual basis. For more details, have a look at the package documentation and maybe `[enit-hspacing]`.

### 12.12 Tables

Tabular material, i.e. material organized into rows and columns, can be typeset using the `tabular` environment (text mode) and the `array` environment (math mode). The `array` package provides an improved implementation of both and its use is assumed in the remainder of this section. Since `tabular` and `array` are basically equivalent in use but the former is much more common, I will only describe the use of `tabular` here.

The `tabular` environment takes one optional and one mandatory argument, like this:  
`\begin{tabular}[\langle position \rangle]{\langle column specification \rangle}`

`\langle position \rangle` can be `t` for top alignment, `b` for bottom alignment or be omitted for middle alignment of the table.

`\langle column specification \rangle` should contain one letter for each column in the table. By default, the column types `l`, `c` and `r` for left, center and right aligned single line columns as well as `p{\langle width \rangle}`, `m{\langle width \rangle}` and `b{\langle width \rangle}` for top, middle and bottom aligned fixed width columns (justified with automatic line breaks) are provided.

Columns are separated by `&`, rows by `\\` [`\langle dimension \rangle`]. The optional argument of `\\` can be used to sometimes add extra vertical space between rows.

```
\begin{tabular}{l c r p{3em} m{3em} b{3em}}
  left & center & right & par & mid & bot \\
x & x & x & x & x & x \\
bla bla bla & bla bla bla & bla bla bla & & & \\
bla bla bla bla bla & bla bla bla bla bla & bla bla bla bla bla & bla bla bla bla bla \\
\end{tabular}
```

left	center	right	par	mid	bot
x	x	x	x	x	x
					bla bla
				bla bla	bla bla
bla bla bla	bla bla bla	bla bla bla	bla bla	bla bla	bla
			bla bla	bla	
			bla		

Additionally, the following characters may appear in the `\langle column specification \rangle`:

| inserts a vertical line. Don't use it (see below).

`@{<stuff>}` inserts `<stuff>` between the adjacent columns in every row instead of the default space of `2\tabcolsep` width. Use `@{}` to remove the column separation.

`!{<stuff>}` inserts `<stuff>` between the adjacent columns in every row in addition to the default space of `\tabcolsep` width on either side. `!{}` won't change anything.

`>{<stuff>}` inserts `<stuff>` at the start of every cell in the successive column.

`<{<stuff>}` inserts `<stuff>` at the end of every cell in the preceding column. Notably, `>` and `<` can be used to switch to and from math mode in every cell of a `tabular` column.

`*{<n>}{<column spec>}` repeats the `<column spec>` (which can contain everything the full specification can) `<n>` times.

```
\begin{tabular}{c @{} c @{\hspace{1cm}} c !{} c
               >{X}c c<{X} >{\(}c<{\)}
               *{3}{>{\color{blue}}c}}
x & x & x & x & x & x & x & x & x & x & x & x \\
a & b & c & d & e & f & g & h & i & j \\
\end{tabular}
```

```
x-x      x - x  Xx  xX  x  x  x  x
a-b      c - d  Xe  fX  g  h  i  j
```

Sometimes a fixed width column with non-justified text. For this, you can define the following additional column specifiers (essentially taken from `[ragged-colspec]`<sup>17</sup>).

```
\newcolumntype{L}[2]{>{\raggedright\let\newline\\\arraybackslash\strut}#1{#2}}
\newcolumntype{C}[2]{>{\centering\let\newline\\\arraybackslash\strut}#1{#2}}
\newcolumntype{R}[2]{>{\raggedleft\let\newline\\\arraybackslash\strut}#1{#2}}
```

They take two arguments, e.g. `L{<prototype>}{<width>}`, where the `<prototype>`, that determines the vertical alignment of the column cells, should be one of `p`, `m` or `b`.

As explained in section 9.5, you should not use many rules in your table and no vertical ones at all. The only rules you should ever need are `\toprule`, `\midrule`, `\bottomrule` and sometimes `\cmidrule`. The rest of the structure of your table can be expressed by careful alignment of its cells.

```
\begin{tabular}{lllc}\toprule
Branch      & Language & Word for Bread & Word for Water & \\
Germanic    & English  & bread          & water          & \\
            & German   & Brot           & Wasser         & \\
            & Norwegian & brød          & vann           & \\
Romance     & Spanish  & pan            & agua           & \\
            & French   & pain           & eau            & \\
Finno-Ugric & Estonian & leib           & vesi           & \\
Slavic      & Slovak   & chlieb         & voda           & \\
\bottomrule\end{tabular}
```

<sup>17</sup><https://tex.stackexchange.com/a/12712>

`\end{tabular}`

Branch	Language	Word for Bread	Word for Water
Germanic	English	bread	water
	German	Brot	Wasser
	Norwegian	brød	vann
Romance	Spanish	pan	agua
	French	pain	eau
Finno-Ugric	Estonian	leib	vesi
Slavic	Slovak	chlieb	voda

If you want to list numeric values in a table, use `siunitx`'s column specifier. You need to tell `siunitx` how much space to allocate for your numbers in every column via the option `table-format`, either using `\sisetup` or in the optional argument of `S`. Specify the `table-format` by writing a number, but instead of the digits of a part of the number you write the maximum number of digits in that part. For example `table-format=-3.2` would allocate space for three digits before and two digits after the decimal point in addition to space for a sign. `table-format=1.3(1)e2` would allocate space for one digit before and three after the decimal point, one digit of uncertainty and two digits in the exponent.

```
\begin{tabular}{c S[table-format=2.3]
                S[table-format=1.2e-1]
                S[table-format=-2]}\toprule
sample & {weight in \si{\kilo\gram}} &
        {resistivity in \si{\ohm}} &
        {voltage in \si{\micro\volt}} \\\midrule
foo & 1.27 & 3e3 & -3 \\\
bar & 13.2 & 1.7e-3 & 0 \\\
baz & 0.138 & 5.66e9 & -74 \\\bottomrule
\end{tabular}
```

sample	weight in kg	resistivity in $\Omega$	voltage in $\mu\text{V}$
foo	1.27	$3 \cdot 10^3$	-3
bar	13.2	$1.7 \cdot 10^{-3}$	0
baz	0.138	$5.66 \cdot 10^9$	-74

For the rare occasion that you need to connect cells horizontally, the `\multicolumn` macro is provided. It takes three arguments: `\multicolumn{<n>}{<colspec>}{<content>}`. `<n>` is the number of columns to connect, `<colspec>` is the specification for the connected column and `<content>` its content.

You never want to connect cells vertically.

### 12.13 Including Images

If you need to include any graphics in your document, load the `graphicx` package. There are really only two macros you absolutely have to know about.

`\includegraphics[⟨options⟩]{⟨filename⟩}` places the graphic `⟨filename⟩` in the document. The file format must be PDF, PNG or JPG, but you don't have to include the file format in `⟨filename⟩`.

The most important options are `width` and `height`, which you can use to scale the image to the desired size. If you use only one of them, the aspect ratio of the graphic is conserved. A typical use case would be

```
\includegraphics[width=.8\textwidth]{cute_cat}
```

`\graphicspath{⟨paths⟩}` sets the paths  $\text{\LaTeX}$  should search when looking for graphics. I usually have an `img/` folder and so I say (note the extra braces)

```
\graphicspath{{./img/}}
```

You can also specify several folders at once:

```
\graphicspath{{./img/setup/}{./img/diagrams/}}
```

If you have SVG drawings, the `svg` package helps you to easily include them into your document via *Inkscape*<sup>18</sup>. I *strongly* recommend setting the `inkscapearea` option to `page` instead of the default `drawing` when loading the package.

```
\usepackage[inkscapearea=page]{svg}
```

A bit of setup is necessary (see [svg-howto]<sup>19</sup>), but after that, the package provides the commands `\includesvg` and `\svgpath` that can essentially be used just like the two commands above, but for SVG drawings. Maybe the biggest advantage of SVG drawings over other graphics formats is that  $\text{\LaTeX}$  typesets any text in the drawing itself. This means that font and font size match the rest of the document and you can use all of the  $\text{\LaTeX}$  symbols and other machinery in your SVG drawing as well. The `pretex` option allows you to insert some  $\text{\LaTeX}$  code before text from the drawing, this is useful if you want to choose the `\small` font for the drawing.

```
\includesvg[width=.6\linewidth, pretex=\small]{cat_drawing}
```

<sup>18</sup><https://inkscape.org/>

<sup>19</sup><https://tex.stackexchange.com/a/523685>

**Figure 1:** The TeX lion [tex-lion].

### 12.14 Floating Content

There are two categories of material that you usually want to put into a floating environment (cf. section 9.6): figures and tables.  $\text{\TeX}$  provides the environments `figure` and `table` for this purpose. These environments are identical except for the counter that is used to number them and the name that is used for their captions. It is easy to define additional floating environments if the need arises, usually this is done by the packages you use to generate the content you want to allow to float, though. For example, both `listings` and `minted` define floating environments for displaying listings.

```
\begin{figure}
  \includesvg[height=6.5cm]{lion}
  \caption{The \TeX\ lion~\cite{web:tex-lion}.}
  \label{fig:tex-lion}
\end{figure}
```

Every floating environment takes an optional argument denoting its preferred placement, e.g. `\begin{figure}[\langle placement \rangle]`. The  $\langle placement \rangle$  may be a sequence of the letters `!` (lift placement restrictions), `h` (here), `t` (top of page), `b` (bottom of page) and `p` (on a float page) in any order (the order doesn't change anything), with the default being `tbp`. Inexperienced users often feel the need to say `[h]` at every float, or even use packages that define `H` to *really* place the “float” exactly where it is in the source file. This is a bad idea (cf. section 9.6). Only check if you need to influence the float placement at the very end, right before publishing.

A floating environment should always contain a `\caption` describing its content and a `\label` that you can use to refer to it in the text (cf. section 12.15). Remember that `\label` has to be placed *after* `\caption`. To avoid errors, it is best to just place it directly after `\caption`.

Table 1: Some natural constants.

Quantity	Symbol	value		Unit
Avogadro constant	$N_{\text{A}}$	6.022 140 76	$\cdot 10^{23}$	$\text{mol}^{-1}$
Planck constant	$h$	6.626 070 15	$\cdot 10^{-34}$	J s
gravitational constant	$G$	6.674 30(15)	$\cdot 10^{-11}$	$\text{m}^3 \text{kg}^{-1} \text{s}^{-2}$
electron mass	$m_{\text{e}}$	9.109 383 701 5(28)	$\cdot 10^{-31}$	kg
proton mass	$m_{\text{p}}$	1.672 621 923 69(51)	$\cdot 10^{-27}$	kg
elementary charge	$e$	1.602 176 634	$\cdot 10^{-19}$	C

Usually, figures and tables are typeset centered in the type area. To achieve this, you can use `\centering` as the first thing in the floating environment. You can make this the default by adding the following to your preamble (etoolbox has to be loaded)

```
% Center all floats by default.
\makeatletter
\appto{@floatboxreset}{\centering}
\makeatother
```

which is what I did and why I didn't have to use `\centering` in the previous (and the next) example.

As noted above, the only difference between `figure` and `table` are their name and numbering. However, it is good practice to place table captions above the table but figure captions below the figure. This accounts for the different ways in which readers read figures opposed to tables.

```
\begin{table}
\caption{Some natural constants.}
\label{tab:natural-constants}
\begin{tabular}{r >{\(}c<{\)} S[table-format=1.11(2)e-2]
>{\collectcell\si}l<{\endcollectcell}}\toprule
Quantity & \multicolumn{1}{c}{Symbol} &
{value} & \multicolumn{1}{l}{Unit} \\ \midrule
Avogadro constant &  $N_{\text{A}}$  & 6.02214076e23 & \per\mole \\
Planck constant &  $h$  & 6.62607015e-34 & \joule\second \\
gravitational constant &  $G$  & 6.67430(15)e-11 &
\cubic\meter\per\kilo\gram\per\square\second \\
electron mass &  $m_{\text{e}}$  & 9.1093837015(28)e-31 & \kilo\gram \\
proton mass &  $m_{\text{p}}$  & 1.67262192369(51)e-27 & \kilo\gram \\
elementary charge &  $e$  & 1.602176634e-19 & \coulomb \\
\end{tabular}
\end{table}
```

When using KOMA-Script, use the document class option `captions=tableheading` to adjust the caption spacing for this convention.

## 12.15 Cross Referencing

Most numbered things in  $\text{\LaTeX}$  are set up to be cross referenced. Whenever you use a command that creates some numbered item, like `\section` or `\caption`, this command prepares some information to be used for cross referencing.

`\label{<label name>}` can be issued *after* any of these commands to store this information under the *<label name>*. Always choose a clear *<label name>* (cf. section 8.2)! I recommend only using letters, numerals and the characters `:` and `-` in the *<label name>*.

`\ref{<label name>}` can be used anywhere in the document to print the number associated with the labeled object, e.g. “1” for section 1.

`\eqref{<label name>}` is like `\ref`, but it formats the number like an equation number. This should, of course, only be used when referencing equations.

`\pageref{<label name>}` can be used anywhere in the document to print the number of the page where the labeled object is located.

`\nameref{<label name>}` can be used anywhere in the document to print the name of the labeled object, if `hyperref` is loaded. This only makes sense for objects that actually have a name (like `\section`).

Remember that you have to compile twice for all labels to be correct (cf. section 4.8).

## 12.16 Citations and Bibliographies

`biblatex` is a very powerful package and we will only list the bare minimum of what you need to know to make it work here.

- You need to load `biblatex` in the preamble. Most of the package configuration can be done separately from loading the package, but there are some options that have to be issued in the optional argument to `\usepackage`. The only one you usually need is `style`, which determines the bibliography and citation style used throughout the document.

```
\usepackage[style=phys]{biblatex}
```

- You can place further configurations directly in the preamble of your document, but since these frequently get a bit lengthy and are often reused in many documents, it is best to write a configuration file. A file named `biblatex.cfg` located in the compilation directory will automatically be read by `biblatex` and can be used for this purpose.
- You need to point `biblatex` to your bibliography database file using the command `\addbibresource{<bibfile>}`. Unlike many other commands pointing to external files, you need to include the file extension in *<bibfile>*.

```
\addbibresource{myliterature.bib}
```

The BIB file itself is most conveniently generated using a bibliography reference manager like JabRef<sup>20</sup>.

- In your document, you can now cite any reference present in your BIB files using citation commands, usually `\cite[⟨page⟩]{⟨key⟩}` or `\footcite[⟨page⟩]{⟨key⟩}`.
- Finally, tell  $\LaTeX$  to print the bibliography using `\printbibliography[⟨options⟩]`.

Remember that in order for all citations and bibliography entries to be up to date you need to call `pdflatex`, then `biber` and then `pdflatex` twice more. Of course, you do not have to do the full cycle every time you compile while writing your document.

## 13 How Macros Really Work

This section contains a very brief description on how macros really work, but not all of the aspects surrounding this are mentioned or explained in detail here. If you want to understand all the nitty gritty minutiae of  $\TeX$ , reading *The  $\TeX$ book* [Knu84] is the way to go (it actually is a good read). If you already know your way around  $\TeX$  and just need a reference, the freely available  *$\TeX$  by Topic* [Eij92] is for you.

Note that I will sometimes use macros and  $\TeX$  primitives in the code examples in this section that are not explained in this document. If you wish to know what exactly they do, please look them up in a reference or search for them online. The examples should however be understandable even without that exact knowledge.

Also note that even though I introduce writing plain  $\TeX$  macros at some length here, you should really only do that if you know what you are doing. Otherwise, it's better to stick to the higher-level programming macros of  $\LaTeX$  2<sub>ε</sub> and  $\LaTeX$  3.

### 13.1 Category Codes

In  $\TeX$ , every character in your source file has a *category code* associated with it. There are 16 of them, but I will only focus on category codes 11 (*letter*; the alphabet, i.e. a through z and A through Z), 12 (*other*; every character that has no special role, like digits and punctuation) and 13 (*active*; these behave like macros). (For most of the other category codes, there is usually only one character with that category code, which make up the list in section 4.1.) As explained in section 4.2, a control sequence is initiated by a backslash (`\`) and contains either only letters or a single non-letter. More precisely, it is initiated by any category 0 character (*escape character*) and contains either only category 12 characters or a single character of any other category.

This is used in  $\LaTeX$  to separate internal commands that should in principal not be used or altered by document authors (though that rule is routinely broken) from user macros. The convention is to have all internal control words contain the character `@`. Since it normally has

<sup>20</sup><https://jabref.org/>

category code 12 (other), it cannot be accidentally used by a document author. In package source code, the category code is changed to 11 (letter) and it can be used in macro names like any letter of the alphabet. You can perform this change yourself using the commands `\makeatletter` and `\makeatother`, which do exactly what they say. So, for example

```
\foo@bar \@gobble
```

usually means “the control word `\foo`, the characters `@`, `b`, `a` and `r`, a space character, the control symbol `\@` and then the characters `g`, `o`, `b`, `b`, `l` and `e` followed by a new line character (which acts like a space)”. When switching category codes first, though,

```
\makeatletter
\foo@bar \@gobble
\makeatother
```

the same sequence of characters in the source means “the control word `\foo@bar` and the control word `\@gobble`”.

The term for a character or control sequence with the category code attached is *token*. When  $\text{\TeX}$  first reads a character on the input stream (the source file), it attaches the currently valid category codes to it, which is called *tokenization*. This happens only once; if category codes change after some character has already been tokenized, that change will not affect that token. A consequence of this is that macros that work by changing category codes, like `\verb`, cannot function inside macro arguments, because the whole argument is tokenized before the macro can change the category codes. For example,

```
\emph{Do not use \verb|\verb| in macro arguments!}
```

will fail.

Now, what about active characters, i.e. those with category code 13? These characters are treated by  $\text{\TeX}$  like a macro, i.e. they can be defined, take arguments and be expanded just like a control sequence. Typical examples of active characters are `~` which is defined to insert a non-breaking space and `"` which babel uses to provide useful shorthands in many languages.

## 13.2 Macro Expansion

When  $\text{\TeX}$  reads your source file, it sees a long string of text, the so-called input stream.  $\text{\TeX}$  starts at the front, with the first token. Let’s assume this is a macro. Then  $\text{\TeX}$  looks up the definition of that macro, takes the macro out of the input stream and inserts its definition instead. If the macro takes any arguments, these are taken out of the input stream together with the macro and may be inserted in appropriate places in its definition. This replacing the macro by its definition is called *expansion*.  $\text{\TeX}$  then looks at the token that is now the first one in the input stream, and so on.

Importantly,  $\text{\TeX}$  only ever tokenizes as many characters from the input stream as necessary. So, at the start of the input stream, there is a number of tokens, i.e. characters that  $\text{\TeX}$  has

already “looked at”, (these are said to be “in T<sub>E</sub>X’s mouth”) while the rest of the input stream remains untouched. New characters are only tokenized when they are at the front of the input stream or when T<sub>E</sub>X needs to scan ahead for something, e.g. macro arguments.

Before we discuss expansion some more, let us first look at how macros can be defined.

### 13.3 Writing Macros: The T<sub>E</sub>X Way

Here, I describe how to define new macros using plain T<sub>E</sub>X. Note that you should only do it this way if you really know what you are doing! Otherwise, it’s better to stick to the higher level possibilities explained below.

`\def<macro name><parameter pattern>{<replacement>}` is the basic command for macro definition. The `<macro name>` can be either a control sequence or an active character. The `<parameter pattern>` specifies how many arguments the macro expects in which form. You can specify up to 9 arguments as #1 through #9. The `<replacement>` can be any sequence of tokens with balanced braces, where #1 through #9 will be replaced with the appropriate argument on expansion.

```
\def\foo#1#2{I saw #2, but first #1.}
\foo{hello}{world}
```

I saw world, but first hello.

`\gdef<macro name><parameter pattern>{<replacement>}` does the same thing as `\def`, but globally, i.e. the definition is not constrained to the current group.

```
\def\foo{one}
\def\baz{two}
\begingroup
  \def\foo{three}
  \gdef\baz{four}
  \foo          \\\
  \baz          \|[2ex]
\endgroup
\foo           \\\
\baz
```

three  
four

one  
four

`\edef<macro name><parameter pattern>{<replacement>}` does the same thing as `\def`, but it fully expands the `<replacement>` first. You will need this if you want to store the current value of some variable for later use.

<code>\def\var{one}</code>		
<code>\def\foo{\var}</code>		one
<code>\edef\baz{\var}</code>		one
<code>\foo</code>	<code>\\</code>	
<code>\baz</code>	<code>\\[2ex]</code>	
<code>\def\var{two}</code>		two
<code>\foo</code>	<code>\\</code>	one
<code>\baz</code>		

`\xdef<macro name><parameter pattern>{<replacement>}` does the same thing as `\edef`, but globally, i.e. the definition is not constrained to the current group.

The `<parameter pattern>` warrants some further explanation. Apart from the argument placeholders #1, #2, etc., it may contain any other tokens (except for braces) that must then be used in the same pattern when the macro is used. If an argument is followed by such a token, it is called *delimited*. An undelimited argument will always only consist of the next available token or brace group. Spaces in front of undelimited arguments will be ignored when  $\text{T}_{\text{E}}\text{X}$  scans for arguments. Both delimited and undelimited arguments will lose one layer of braces on expansion.

<code>\def\foo#1#2{[#1::#2]}</code>		[h::e]llo world
<code>\foo hello world</code>	<code>\\</code>	[h::ello] world
<code>\foo h{ello} world</code>	<code>\\</code>	[hello::w]orld
<code>\foo{hello}world</code>	<code>\\</code>	[hello::world]
<code>\foo{hello}{world}</code>	<code>\\</code>	[hello::world]
<code>\foo {hello} {world}</code>	<code>\\[2ex]</code>	[hello::world]
<code>\def\foo#1#2r{[#1::#2]}</code>		
<code>\foo hello world</code>	<code>\\</code>	[h::ello wo]ld
<code>\foo{hello}world</code>	<code>\\[2ex]</code>	[hello::wo]ld
<code>\def\foo#1#2\foo{\baz #1 and \baz #2}</code>		
<code>\def\baz#1{[#1]}</code>		[h] and [e]llo world
<code>\foo hello world\foo</code>	<code>\\</code>	[h]ello and [w]orld
<code>\foo{hello}world\foo</code>	<code>\\</code>	[hello] and [w]orld
<code>\foo{{hello}}{world}\foo</code>	<code>\\</code>	[hello] and [world]
<code>\foo{{hello}}{{world}}\foo</code>		

If you want the expansion of a macro to contain a #, you need to escape it in the definition using another #, otherwise  $\text{T}_{\text{E}}\text{X}$  will expect it to be part of an argument placeholder.

```

\def\foo#1{%
  \def\baz##1{Try #1 with ##1!}%
}
\foo{Nutella}
\baz{banana}          \\
\baz{peanut butter}   \\
\baz{fruit yoghurt}   \\[2ex]
\foo{peanut butter}
\baz{banana}          \\
\baz{honey}

```

Try Nutella with banana!  
 Try Nutella with peanut butter!  
 Try Nutella with fruit yoghurt!  
  
 Try peanut butter with banana!  
 Try peanut butter with honey!

There are two varieties of macros in T<sub>E</sub>X, called *short* and *long*. Short macros (which is the default) will not accept arguments containing a paragraph break (`\par` or equivalently a blank line), long macros do not have this restriction. This may be useful when you forget a closing brace or an argument delimiter, which causes T<sub>E</sub>X to scan ahead until it finds a matching one (or the document ends). If the macro is defined as short, T<sub>E</sub>X will stop scanning when it encounters a `\par` and complain about it. As this can otherwise lead to rather surprising behavior and errors, it is best not to make macros long if they should never receive entire paragraphs as arguments anyway. To make a macro long, just prefix `\long` to its definition, i.e. use `\long\def` instead of `\def`, etc.

Sometimes, you want to create a copy of a macro under a different name.

`\let<commanda><commandb>` makes `<macroa>` a copy of `<commandb>`. As with `\def`, both control sequences and active characters work.

```

\def\foo#1{I saw #1.}
\def\baz{\foo}
\let\foocopy\foo
\foo{fire}           \\
\baz{fire}           \\
\foocopy{fire}       \\[2ex]
\def\foo#1{Give me #1 or else.}
\foo{fire}           \\
\baz{fire}           \\
\foocopy{fire}

```

I saw fire.  
 I saw fire.  
 I saw fire.  
  
 Give me fire or else.  
 Give me fire or else.  
 I saw fire.

There is no `\glet` command, instead you have to prepend `\global`, i.e. use `\global\let` instead of `\let`, in order to make the assignment globally.

So, what about optional arguments, you may ask. Well, there really are no optional arguments at all in T<sub>E</sub>X. L<sup>A</sup>T<sub>E</sub>X only creates the illusion of optional argument using a construction like this one.

```

\makeatletter
\def\foo{\@ifnextchar[{\foo@aux}{\foo@aux[that]}}
\def\foo@aux[#1]#2{My name is #2, please call me #1.}
\makeatother

```

```
\foo{Paul}          \\  
\foo[Sam]{Samantha}
```

My name is Paul, please call me that.

My name is Samantha, please call me Sam.

The macro `\@ifnextchar⟨char⟩{⟨true code⟩}{⟨false code⟩}` checks if the next character following it is `⟨char⟩`. If so, it leaves `⟨true code⟩` in the input stream, otherwise `⟨false code⟩`. Using this, `\foo` first checks if an optional argument is present and inserts the default if there is none. Then, the auxiliary macro `\foo@aux` does the actual thing you called `\foo` for.

So, what we call *optional arguments* in  $\text{\TeX}$  are checks for an opening bracket combined with an auxiliary macro scanning for an argument enclosed in brackets. What we call *mandatory arguments* are just normal, undelimited arguments. There are two important consequences of this

- You cannot use a closing bracket in an optional argument, as  $\text{\TeX}$  will interpret it as the closing bracket of that argument (unlike with braces,  $\text{\TeX}$  does not know the concept of matching brackets). If you do want to use an optional argument containing a closing bracket, you will have to enclose it in a brace group. For example, with the definition of `\foo` above, `\foo[[]]{brackets}` will fail while `\foo[{[]}]{brackets}` will succeed.
- The braces around mandatory arguments are in fact optional if the argument consist of a single token. It is considered good practice to use the braces anyway, because it clarifies which tokens are macro arguments and which aren't. Especially if you are not totally sure of when you need and when you needn't use braces, you should just always use them. As you become more familiar with  $\text{\TeX}$ , though, you may find it tiresome to always type the braces for common macros that usually apply to only one token, and move on to writing e.g. `\vec s` instead of `\vec{s}`. This is fine, in my opinion, as long as you stay consistent and use braces when it may be confusing otherwise (for example I'd say that `\frac 12` is fine but `\frac{a_n} 2` is not). The only arguments I'd recommend *not* enclosing in braces are those that must receive exactly one token, e.g. the first argument of `\newcommand`.

### 13.4 Expandability and Robustness

When I discussed macro expansion above, I omitted the question of what happens when the token at the front of the input stream is not a macro.  $\text{\TeX}$  may “swallow” the token to put it into the box it is currently building for output on the page (e.g. if the token is the letter `a` or the character `!`). If the token is a  $\text{\TeX}$  primitive, then it depends. Some primitives are expanded (remember this means that they only change the input stream), others need to be executed, e.g. for defining macros or setting a dimension register. All the tokens that affect other things than just the input stream when handled, i.e. everything except macros and the expandable primitives, are called *unexpandable*.

Usually, this distinction does not matter much, because  $\text{\TeX}$  will just do whatever the token at the beginning of the input stream demands. However, there are some contexts in which

$\text{\TeX}$  works in *expansion-only mode*, most notably when writing to files or inside an  $\text{\edef}$  or  $\text{\xdef}$ . In these contexts,  $\text{\TeX}$  will happily leave any unexpandable tokens be and move on to the next one.

This can lead to problems when a macro relies on something being executed before something else is expanded. Here’s an example.

<pre> \makeatletter \@tempcnta=0\relax \def\foo{%   \advance\@tempcnta by 1\relax   I like the number \the\@tempcnta.% } \makeatother \foo           \\\ \foo           \\\ \foo           \\\[2ex] \edef\baz{\foo} \baz           \\\ \baz           \\\ \foo </pre>	<pre> I like the number 1. I like the number 2. I like the number 3.  I like the number 3. I like the number 3. I like the number 6. </pre>
---	---

The macro  $\text{\foo}$  first increases the count register  $\text{\@tempcnta}$  by one using  $\text{\advance}$  and then prints out a sentence using the current value of that count register. This works fine as long as  $\text{\foo}$  is used in the standard typesetting mode. After saying  $\text{\edef\baz{\foo}}$  you may have expected  $\text{\baz}$  to have the expansion *I like the number 4.*, however it actually prints “*I like the number 3.*” and furthermore has an unintended interaction with the behavior of  $\text{\foo}$ . Why does this happen?

The key to understanding this is knowing that the only expandable token in the definition of  $\text{\foo}$  is  $\text{\the}$ . It consumes the count register  $\text{\@tempcnta}$  and expands to its current value. All the other tokens are not touched by the  $\text{\edef}$  expansion.  $\text{\baz}$  thus always prints the value  $\text{\@tempcnta}$  had when it was defined while increasing the value of that register every time it is used.

Commands that break down when used in an expansion-only context are called *fragile*. While the example above is rather silly, it shows that using fragile commands in an expansion-only context can lead to unexpected results. More often than not, it will cause  $\text{\TeX}$  to fail immediately, which is certainly better than producing unintended results, but the error messages may be hard to connect to the underlying issue of expandability.

The solution to this problem is to make the problematic macros *robust* by *protecting* them from being expanded in the wrong place. In  $\text{\LaTeX 2}_{\epsilon}$ , this was done using the macro  $\text{\protect}$  in front of fragile commands and defining it to do nothing normally, but redefining it to prevent the following token from being expanded in the appropriate places. This is explained in a bit more detail in [fragile-robust]<sup>21</sup>, but you don’t really need to know about all that, because  $\text{\LaTeX}$  has protection as a native concept. It introduced the  $\text{\protected}$  primitive,

<sup>21</sup><https://tex.stackexchange.com/a/4747>

which you can prepend to a macro definition to make it robust. Macros defined this way will not be expanded in an expansion-only context.

```
\makeatletter
\@tempcnta=0\relax
\def\foo{%
  \advance\@tempcnta by 1\relax
  I like the number \the\@tempcnta.%
}
\protected\def\betterfoo{%
  \advance\@tempcnta by 1\relax
  I like the number \the\@tempcnta.%
}
\makeatother
\edef\baz{\foo}
\edef\betterbaz{\betterfoo}
\ttfamily
\meaning\baz          \
\meaning\betterbaz
```

```
macro:->\advance \@tempcnta by 1\relax I like the number 0.
macro:->\betterfoo
```

It is best to make every macro either protected or fully expandable. In  $\text{\LaTeX} 2_{\epsilon}$  this is a bit of a hassle, because the syntax for defining robust and fragile commands is not consistent. So, if you are just writing a few small macros, I'd say don't worry about this rule too much. In  $\text{\LaTeX} 3$  however, this separation is implemented consequently and should be followed.

### 13.5 Writing Macros: The $\text{\LaTeX} 2_{\epsilon}$ Way

$\text{\LaTeX} 2_{\epsilon}$  provides the following commands to define macros instead of with `\def`.

`\newcommand<macro name>[<nargs>][<default>]{<replacement>}` checks if `<macro name>` is already defined. If it is, it issues an error, otherwise it defines it. `<nargs>` is the number of arguments the new macro should take and can be a value from 1 to 9. If `<default>` is given, the first argument (`#1`) is optional and has the value `<default>` when it is not given.

```
\newcommand\foo[2][that]{My name is #2, please call me #1.}
\foo{Paul}          \
\foo[Sam]{Samantha}
```

```
My name is Paul, please call me that.
My name is Samantha, please call me Sam.
```

`\renewcommand<macro name>[<nargs>][<default>]{<replacement>}` does the same thing, but instead expects `<macro name>` to already be defined and issues an error otherwise.

`\providecommand⟨macro name⟩[⟨nargs⟩][⟨default⟩]{⟨replacement⟩}` checks if `⟨macro name⟩` is taken. If so, it does nothing without complaining, otherwise it defines the macro just like `\newcommand`.

An environment `foo` is made up of two macros, `\foo` and `\endfoo`. When the environment is started using `\begin{foo}`, some bookkeeping is done and finally `\foo` is expanded. Conversely, `\end{foo}` expands to `\endfoo` with some bookkeeping. Note that this means that you cannot define both an environment `foo` and a macro `\foo`. To define environments, the following macros are available.

`\newenvironment{⟨environment name⟩}[⟨nargs⟩][⟨default⟩]{⟨begin code⟩}{⟨end code⟩}` works just like `\newcommand`, but it defines an environment. The `⟨begin code⟩` will be executed at the start of the environment, the `⟨end code⟩` at its end. Note that you can only use the arguments in the `⟨begin code⟩`.

`\renewenvironment{⟨environment name⟩}[⟨nargs⟩][⟨default⟩]{⟨begin code⟩}{⟨end code⟩}` does the same, but for environments that were already defined (like `\renewcommand`).

All of these commands create long macros by default. To define a short one, use the starred variant (`\newcommand*`, etc.) instead. While this syntax encourages the creation of long macros, I suggest only doing so when needed (as explained above).

## 13.6 Writing Macros: The L<sup>A</sup>T<sub>E</sub>X3 Way

In L<sup>A</sup>T<sub>E</sub>X3, the programming layer used for writing complex macros and packages is clearly separated from the user commands to be used by document authors. This separation as well as the naming conventions mentioned below are purely by convention; under the hood, everything still runs on T<sub>E</sub>X. They do however make it much easier to create complex commands and handle data in a more natural way as well as create user commands with a flexible interface of different kinds of arguments.

Because of the extensiveness of the L<sup>A</sup>T<sub>E</sub>X3 concepts, the description provided here will not come close to enabling you to use them. For that, you will have to read the proper documentation.

### 13.6.1 Creating User Commands Using xparse

The `xparse` package lets you easily define user commands with both undelimited and delimited, mandatory as well as optional arguments with or without default values. Starred variants (or in fact other optional characters in the argument syntax) as well as *embellishments* are easily specified as well. It also introduces *argument preprocessors* that can be used to regularize user input before it is passed to the macro's code. Please have a look at the `xparse` documentation for a detailed description of its features and syntax. Here, I only want to show a short example showing off some of its features.

`\NewDocumentCommand⟨function⟩{⟨arg spec⟩}{⟨code⟩}` checks if `⟨function⟩` is already defined and defines it otherwise. The power of `xparse` lies in the many possible argument types you can use in `⟨arg spec⟩`.

Let us write a function `\newcmdsyntax` that tells us what a certain `\newcommand` call would do.

```
\NewDocumentCommand\newcmdsyntax{s m o o v}{%
  \texttt{%
    \string\newcommand
    \IfBooleanT{#1}{*}%
    \string #2%
    \IfValueT{#3}{[#3]\IfValueT{#4}{[\detokenize{#4}]}}%
    \{#5\}%
  }
  defines a new \IfBooleanTF{#1}{short}{long} macro \texttt{\string #2}
  \IfValueT{#3}{%
    with #3 arguments%
    \IfValueT{#4}{%
      , where the first one is optional with the default value
      '\texttt{#4}',%
    }
  }%
  that expands to '\ttfamily\detokenize{#5}''.%
}

\newcmdsyntax*\foo{Hello World!} \\\
\newcmdsyntax*\foo[1]{I saw #1.} \\\
\newcmdsyntax\foo[2][that]{My name is #2, please call me #1.}
```

`\newcommand*\foo{Hello World!}` defines a new short macro `\foo` that expands to ‘Hello World!’.

`\newcommand*\foo[1]{I saw #1.}` defines a new short macro `\foo` with 1 arguments that expands to ‘I saw #1.’.

`\newcommand\foo[2][that]{My name is #2, please call me #1.}` defines a new long macro `\foo` with 2 arguments, where the first one is optional with the default value ‘that’, that expands to ‘My name is #2, please call me #1.’.

While the `xparse` functions are intended to eventually only be used to create user interfaces to the underlying programming layer (see below), for now you can also use it as a more powerful replacement to the  $\text{\LaTeX}$  2<sub>ε</sub> macro creation commands.

### 13.6.2 Programming Using `expl3`

The  $\text{\LaTeX}$  3 programming layer is contained in the `expl3` package and explained in its documentation, the built-in functions and variables are described in [interface3]. All this is much to extensive to describe here in detail, so only the very broad strokes will be mentioned.

- `expl3` programming takes place in a special category code regime, which you can enter with `\ExplSyntaxOn` and leave with `\ExplSyntaxOff` (much like `\makeatletter` and `\makeatother`). In this category code regime, `_` and `:` are letters, spaces and newlines are ignored, and `~` inputs a space. This means that spaces can liberally be used to

organize your code without worrying about spurious spaces (cf. the previous code example). `_` and `:` are used to give structure to macro names.

- A distinction between *functions* and *variables* is introduced. While this distinction is purely artificial (after all, this is still  $\text{T}_{\text{E}}\text{X}$ , a macro expansion language), it is more natural to think in these terms. The idea is to separate macros that contain data (variables) from macros that contain code (functions).
- A clear naming scheme is used for both functions and variables.
  - ◊ `\<module>_<description>:<signature>` for functions and
  - ◊ `\<scope>_<module>_<description>_<type>` for variables.

This naming scheme effectively allows functions to be overloaded and variables to be organized into global, local and constant ones.

- Several variable types together with functions to manipulate these variables as well as powerful expansion control capabilities are provided.

If you have never attempted to program anything in  $\text{T}_{\text{E}}\text{X}$ , these points may not mean much to you. Trust me, these concepts vastly simplify this task. As a demonstration, here is a small program that I was able to pretty much just bang out using  $\text{L}_{\text{A}}\text{T}_{\text{E}}\text{X}3$ , that you can probably understand immediately (well, after some getting used to the naming scheme). In plain  $\text{T}_{\text{E}}\text{X}$ , which is the way programs were written for  $\text{L}_{\text{A}}\text{T}_{\text{E}}\text{X}2_{\epsilon}$ , this would taken much more effort, and the result would be much harder to comprehend.

```
\ExplSyntaxOn
\cs_new:Nn \beneiii_gcd:nn
{
  \int_compare:nNnTF { #1 } > { #2 }
  { \__beneiii_gcd:nn { #1 } { #2 } }
  { \__beneiii_gcd:nn { #2 } { #1 } }
}
\cs_new:Nn \__beneiii_gcd:nn
{
  \int_compare:nNnTF { #2 } = 0
  { #1 }
  {
    \__beneiii_gcd:ee
    { #2 }
    { \int_mod:nn { #1 } { #2 } }
  }
}
\cs_generate_variant:Nn \__beneiii_gcd:nn { ee }
\cs_new:Nn \beneiii_reduced_frac:nn
{
  \beneiii_canceled_frac:nne
  { #1 } { #2 } { \beneiii_gcd:nn { #1 } { #2 } }
}
```

```

\cs_new:Nn \beneiii_canceled_frac:nnn
{
  \beneiii_frac:ee
  { \int_div_truncate:nn { #1 } { #3 } }
  { \int_div_truncate:nn { #2 } { #3 } }
}
\cs_generate_variant:Nn \beneiii_canceled_frac:nnn { nne }
\cs_new:Nn \beneiii_frac:nn
{
  \int_compare:nNnTF { #2 } = 1
  { #1 }
  { \frac{ #1 }{ #2 } }
}
\cs_generate_variant:Nn \beneiii_frac:nn { ee }
\NewDocumentCommand \reducedfrac { m m }
{ \beneiii_reduced_frac:nn { #1 } { #2 } }
\ExplSyntaxOff

\begin{align*}
\frac{27}{6} &= \reducedfrac{27}{6} &
\frac{31611}{57054} &= \reducedfrac{31611}{57054} &
\frac{27699}{3957} &= \reducedfrac{27699}{3957} \\
\end{align*}

```

$$\frac{27}{6} = \frac{9}{2}$$

$$\frac{31611}{57054} = \frac{41}{74}$$

$$\frac{27699}{3957} = 7$$

## 14 Getting Help

$\text{\LaTeX}$  can be confusing at times and the vastness of its features can leave users a bit lost. Luckily, there are many resources that can help you with this.

### 14.1 How Can I Produce This Symbol?

Traditionally, the way to look up symbols is by looking through *The Comprehensive  $\text{\LaTeX}$  Symbol List* [comprehensive]. It lists symbols sorted by category and package. If you want to look up symbols of a certain category or compare different versions of the same symbol (provided by different packages), it is still the way to go.

If you know the shape of the symbol and just have to figure out how to produce it, though, *Detexify*<sup>22</sup> is much more useful. There, you can just draw your symbol and it will point you to the right packages and commands. For those who prefer drawing on their phone to the computer, there even is an app.

<sup>22</sup><https://detexify.kirelabs.org/classify.html>

Some more resources for finding symbols for use with unicode-math are mentioned in [finding-symbols]<sup>23</sup>.

## 14.2 How Does This Package Work?

As a general rule, RTFM! Most common  $\text{\LaTeX}$  packages come with very fine documentation indeed. You can easily find it on CTAN<sup>24</sup>, but it is also installed on your local machine with each package. The `texdoc` utility is the most convenient way of accessing this local documentation [texdoc]. Just type `texdoc <package>` in your system's command line to access the documentation of any installed `<package>`.

While reading the documentation is the ultimate way to learn about a package, sometimes it is useful to just look at an example to get started. Many packages provide minimal (and sometimes advanced) examples in or alongside their documentation, but it can still be useful to search for some online or ask your fellow  $\text{\TeX}$ ers for one. Just remember that what other people show you is not always the best way to go about things.

## 14.3 I'm Getting Lots of Errors!

Sometimes, you just need to compile again for the errors to disappear. This can happen when you change something in your document that first needs to propagate through the auxiliary files (loading `hyperref` is a typical example). When in doubt, just try compiling twice without changing anything in between.

When actual errors appear, it's usually a whole bunch at once. This is because when  $\text{\TeX}$  finds an error, it has no way of determining where the erroneous piece of code ends, and it just plows on. This in turn often causes a whole cascade of errors before  $\text{\TeX}$  finally stops. Fixing the original error will usually prevent that cascade from starting and thus remove all error messages at once.

So, when you get errors, always look only at *the first* one and fix that first. Chances are, it's the only real one. Carefully read the error message (many editors try to parse error messages and sometimes miss some part of it, so you may want to look at the error message in the log file; in  $\text{\TeX}$ studio you can do that by clicking the Log button in the tab of the same name). Many times, it tells you what's wrong. Sometimes, however, you get infamously cryptic error messages and can't really know what they mean without prior experience. In these cases, searching for the error message online usually leads you to the right solution.

## 14.4 I Still Need Help!

Well, that's okay. The best address for finding  $\text{\LaTeX}$  help online is the  *$\text{\TeX}$ – $\text{\LaTeX}$  Stack Exchange*<sup>25</sup>, where you will find many questions already answered and some competent experts to answer new ones. Helpful links can also be found on the websites of *The  $\text{\LaTeX}$*

<sup>23</sup><https://tex.stackexchange.com/a/21>

<sup>24</sup><https://ctan.org/>

<sup>25</sup><https://tex.stackexchange.com/>

*Project*<sup>26</sup> and *DANTE e.V.*<sup>27</sup> (in German). If you are looking for a  $\text{\TeX}$  reference in book form, *The  $\text{\TeX}$  Companion* [Mit+04] may be for you.

Of course, asking your local  $\text{\TeX}$  sage for help is always a good option as well. I, for one, will be glad to help.

## 15.2 References

The literature listed here consists mainly of package documentation and other manuals and references that are available on *CTAN* and via the `texdoc` utility. If the label of the bibliography entry is not a shortened form of author and year of the entry, you can find it using this name. For example, you can find *The Comprehensive L<sup>A</sup>T<sub>E</sub>X Symbol List* (which has the label [comprehensive]) by typing `texdoc comprehensive` in the command line or by searching for “comprehensive” on [ctan.org](https://ctan.org). (Of course, you will only find documentation of a package using `texdoc` if the package is installed on your machine.)
